New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Tim Daly
CAISS, City College of New York
November 10, 2003 ((iHy))

Chapter 1

Chapter Overview

This book contains the domains in Axiom, in alphabetical order.

Each domain has an associated 'dotpic' chunk which only lists the domains, categories, and packages that are in the layer immediately below in the build order. For the full list see the algebra Makefile where this information is maintained.

Each domain is preceded by a picture. The picture indicates several things. The colors indicate whether the name refers to a category, domain, or package. An ellipse means that the name refers to something in the bootstrap set. Thus,

AlgebraGivenByStructuralConstants examples
=====

```

`AlgebraGivenByStructuralConstants` implements finite rank algebras over a commutative ring, given by the structural constants `gamma` with respect to a fixed basis `[a1,...,an]`, where `gamma` is an `n`-vector of `n` by `n` matrices `[(gamma_ijk) for k in 1..rank()]` defined by

$$a_i * a_j = \text{gamma}_{ij1} * a_1 + \dots + \text{gamma}_{ijn} * a_n$$

The symbols for the fixed basis have to be given as a list of symbols.

— Any.help —

Any examples

Any implements a type that packages up objects and their types in objects of Any. Roughly speaking that means that if $s : S$ then when converted to Any, the new object will include both the original object and its type. This is a way of converting arbitrary objects into a single type without losing any of the original information. Any object can be converted to one of Any.

So we can convert a list to type Any

```

a:Any := [1,2]
      [1,2]

```

and another list to type Any

```

b:Any := [1,2]
      [1,2]

```

Equality works

```
(a = b)@Boolean
true
```

We can compare the Any type with other types:

```
c := [1,2]
```

```
typeof a
```

```
typeof c
```

```
(a = c)@Boolean
```

If the values are different than we see the difference:

```
b := [1,3]
[1,3]
```

```
(a = b)@Boolean
false
```

The Any type works with many types:

```
a := "A"
"A"
```

```
(a = b)@Boolean
false
```

```
b := "A"
"A"
```

```
(a = b)@Boolean
true
```

This is true for more complex types:

```
Sae := SAE(FRAC INT, UP(x, FRAC INT), x^2-3)
```

```
a := generator()$Sae
x
```

```
b := generator()$Sae
x
```

```
(a = b)@Boolean
true
```

— domain ANY Any —

```
)abbrev domain ANY Any
++ Author: Robert S. Sutor
++ Description:
++ \spadtype{Any} implements a type that packages up objects and their
++ types in objects of \spadtype{Any}. Roughly speaking that means
++ that if \spad{s : S} then when converted to \spadtype{Any}, the new
++ object will include both the original object and its type. This is
++ a way of converting arbitrary objects into a single type without
++ losing any of the original information. Any object can be converted
++ to one of \spadtype{Any}.
```

```
Any(): SetCategory with
  any          : (SExpression, None) -> %
  ++ any(type,object) is a technical function for creating
  ++ an object of \spadtype{Any}. Arugment \spad{type} is a
  ++ \spadgloss{LISP} form for the type of \spad{object}.
  domainOf     : % -> OutputForm
  ++ domainOf(a) returns a printable form of the type of the
  ++ original object that was converted to \spadtype{Any}.
```

```

objectOf      : % -> OutputForm
++ objectOf(a) returns a printable form of the
++ original object that was converted to \spadtype{Any}.
dom           : % -> SExpression
++ dom(a) returns a \spadgloss{LISP} form of the type of the
++ original object that was converted to \spadtype{Any}.
obj           : % -> None
++ obj(a) essentially returns the original object that was
++ converted to \spadtype{Any} except that the type is forced
++ to be \spadtype{None}.
showTypeInOutPut: Boolean -> String
++ showTypeInOutPut(bool) affects the way objects of
++ \spadtype{Any} are displayed. If \spad{bool} is true
++ then the type of the original object that was converted
++ to \spadtype{Any} will be printed. If \spad{bool} is
++ false, it will not be printed.

=====

ArrayStack examples

=====

An ArrayStack object is represented as a list ordered by last-in, first-out. It operates like a pile of books, where the "next" book is the one on the top of the pile.

Here we create an array stack of integers from a list. Notice that the order in the list is the order in the stack.

```

a:ArrayStack INT:= arrayStack [1,2,3,4,5]
[1,2,3,4,5]

```

We can remove the top of the stack using pop!:

```

pop! a
1

```

Notice that the use of pop! is destructive (destructive operations in Axiom usually end with ! to indicate that the underlying data structure is changed).

```

a
[2,3,4,5]

```

The `extract!` operation is another name for the `pop!` operation and has the same effect. This operation treats the stack as a `BagAggregate`:

```
extract! a
2
```

and you can see that it also has destructively modified the stack:

```
a
[3,4,5]
```

Next we push a new element on top of the stack:

```
push!(9,a)
9
```

Again, the `push!` operation is destructive so the stack is changed:

```
a
[9,3,4,5]
```

Another name for `push!` is `insert!`, which treats the stack as a `BagAggregate`:

```
insert!(8,a)
[8,9,3,4,5]
```

and it modifies the stack:

```
a
[8,9,3,4,5]
```

The `inspect` function returns the top of the stack without modification, viewed as a `BagAggregate`:

```
inspect a
8
```

The `empty?` operation returns true only if there are no element on the stack, otherwise it returns false:

```
empty? a
false
```

The `top` operation returns the top of stack without modification, viewed as a `Stack`:

```
top a
8
```

The depth operation returns the number of elements on the stack:

```
depth a
5
```

which is the same as the # (length) operation:

```
#a
5
```

The less? predicate will compare the stack length to an integer:

```
less?(a,9)
true
```

The more? predicate will compare the stack length to an integer:

```
more?(a,9)
false
```

The size? operation will compare the stack length to an integer:

```
size?(a,#a)
true
```

and since the last computation must always be true we try:

```
size?(a,9)
false
```

The parts function will return the stack as a list of its elements:

```
parts a
[8,9,3,4,5]
```

If we have a BagAggregate of elements we can use it to construct a stack. Notice that the elements are pushed in reverse order:

```
bag([1,2,3,4,5])$ArrayStack(INT)
[5,4,3,2,1]
```

The empty function will construct an empty stack of a given type:

```
b:=empty()$(ArrayStack INT)
[]
```

and the empty? predicate allows us to find out if a stack is empty:

```
empty? b
true
```

The sample function returns a sample, empty stack:

```
sample()$ArrayStack(INT)
[]
```

We can copy a stack and it does not share storage so subsequent modifications of the original stack will not affect the copy:

```
c:=copy a
[8,9,3,4,5]
```

The eq? function is only true if the lists are the same reference, so even though c is a copy of a, they are not the same:

```
eq?(a,c)
false
```

However, a clearly shares a reference with itself:

```
eq?(a,a)
true
```

But we can compare a and c for equality:

```
(a=c)@Boolean
true
```

and clearly a is equal to itself:

```
(a=a)@Boolean
true
```

and since a and c are equal, they are clearly NOT not-equal:

```
a~=c
false
```

We can use the any? function to see if a predicate is true for any element:

```
any?(x+>(x=4),a)
true
```

or false for every element:

```
any?(x+>(x=11),a)
false
```

We can use the every? function to check every element satisfies a predicate:

```
every?(x+>(x=11),a)
false
```

We can count the elements that are equal to an argument of this type:

```
count(4,a)
1
```

or we can count against a boolean function:

```
count(x+>(x>2),a)
5
```

You can also map a function over every element, returning a new stack:

```
map(x+>x+10,a)
[18,19,13,14,15]
```

Notice that the original stack is unchanged:

```
a
[8,9,3,4,5]
```

You can use `map!` to map a function over every element and change the original stack since `map!` is destructive:

```
map!(x+>x+10,a)
[18,19,13,14,15]
```

Notice that the original stack has been changed:

```
a
[18,19,13,14,15]
```

The `members` function can also get the element of the stack as a list:

```
members a
[18,19,13,14,15]
```

and using `member?` we can test if the stack holds a given element:

```
member?(14,a)
true
```

Asp29 examples

=====

Asp29 produces Fortran for Type 29 ASPs, needed for NAG routine f02fjf,
for example:

```
SUBROUTINE MONIT(ISTATE,NEXTIT,NEVALS,NEVECS,K,F,D)
DOUBLE PRECISION D(K),F(K)
```

```

INTEGER K,NEXTIT,NEVALS,NVECS,ISTATE
CALL F02FJZ(ISTATE,NEXTIT,NEVALS,NEVECS,K,F,D)
RETURN
END

```

=====

Asp41 examples

=====

Asp41 produces Fortran for Type 41 ASPs, needed for NAG routines d02raf and d02saf in particular. These ASPs are in fact three Fortran routines which return a vector of functions, and their derivatives wrt Y(i) and also a continuation parameter EPS, for example:

```

SUBROUTINE FCN(X,EPS,Y,F,N)
DOUBLE PRECISION EPS,F(N),X,Y(N)
INTEGER N
F(1)=Y(2)
F(2)=Y(3)

```

```

F(3)=(-1.0D0*Y(1)*Y(3))+2.0D0*EPS*Y(2)**2+(-2.0D0*EPS)
RETURN
END
SUBROUTINE JACOB(X, EPS, Y, F, N)
DOUBLE PRECISION EPS, F(N, N), X, Y(N)
INTEGER N
F(1,1)=0.0D0
F(1,2)=1.0D0
F(1,3)=0.0D0
F(2,1)=0.0D0
F(2,2)=0.0D0
F(2,3)=1.0D0
F(3,1)=-1.0D0*Y(3)
F(3,2)=4.0D0*EPS*Y(2)
F(3,3)=-1.0D0*Y(1)
RETURN
END
SUBROUTINE JACEPS(X, EPS, Y, F, N)
DOUBLE PRECISION EPS, F(N), X, Y(N)
INTEGER N
F(1)=0.0D0
F(2)=0.0D0
F(3)=2.0D0*Y(2)**2-2.0D0
RETURN
END

```

=====

Asp42 examples

=====

Asp42 produces Fortran for Type 42 ASPs, needed for NAG routines d02raf and d02saf in particular. These ASPs are in fact three Fortran routines which return a vector of functions, and their derivatives wrt Y(i) and also a continuation parameter EPS, for example:

```

SUBROUTINE G(EPS,YA,YB,BC,N)
DOUBLE PRECISION EPS,YA(N),YB(N),BC(N)
INTEGER N
BC(1)=YA(1)
BC(2)=YA(2)
BC(3)=YB(2)-1.0D0
RETURN
END
SUBROUTINE JACOBG(EPS,YA,YB,AJ,BJ,N)
DOUBLE PRECISION EPS,YA(N),AJ(N,N),BJ(N,N),YB(N)
INTEGER N
AJ(1,1)=1.0D0
AJ(1,2)=0.0D0
AJ(1,3)=0.0D0

```

```

AJ(2,1)=0.0D0
AJ(2,2)=1.0D0
AJ(2,3)=0.0D0
AJ(3,1)=0.0D0
AJ(3,2)=0.0D0
AJ(3,3)=0.0D0
BJ(1,1)=0.0D0
BJ(1,2)=0.0D0
BJ(1,3)=0.0D0
BJ(2,1)=0.0D0
BJ(2,2)=0.0D0
BJ(2,3)=0.0D0
BJ(3,1)=0.0D0
BJ(3,2)=1.0D0
BJ(3,3)=0.0D0
RETURN
END
SUBROUTINE JACGEP(EPS,YA,YB,BCEP,N)
DOUBLE PRECISION EPS,YA(N),YB(N),BCEP(N)
INTEGER N
BCEP(1)=0.0D0
BCEP(2)=0.0D0
BCEP(3)=0.0D0
RETURN
END

```

=====

Asp9 examples

=====

Asp9 produces Fortran for Type 9 ASPs, needed for NAG routines
d02bhf, d02cjf, d02ejf.
These ASPs represent a function of a scalar X and a vector Y, for example:

```

DOUBLE PRECISION FUNCTION G(X,Y)
DOUBLE PRECISION X,Y(*)
G=X+Y(1)
RETURN
END

```

If the user provides a constant value for G, then extra information is added
via COMMON blocks used by certain routines. This specifies that the value
returned by G in this case is to be ignored.

)abbrev domain ASP9 Asp9
++ Author: Mike Dewar, Grant Keady and Godfrey Nolan
++ Date Created: Mar 1993
++ Date Last Updated: 6 October 1994
++ Description:
++ \spadtype{Asp9} produces Fortran for Type 9 ASPs, needed for NAG routines
++ d02bhf, d02cjf, d02ejf.
++ These ASPs represent a function of a scalar X and a vector Y, for example:
++
++ \tab{5}DOUBLE PRECISION FUNCTION G(X,Y)\br
++ \tab{5}DOUBLE PRECISION X,Y(*)\br
++ \tab{5}G=X+Y(1)\br
++ \tab{5}RETURN\br
++ \tab{5}END
++
++ If the user provides a constant value for G, then extra information is added
++ via COMMON blocks used by certain routines. This specifies that the value
++ returned by G in this case is to be ignored.
  
```

```

=====
AssociatedJordanAlgebra examples
=====

```

AssociatedJordanAlgebra takes an algebra A and uses *\$A to define the new multiplications

$$a*b := (a *$A b + b *$A a)/2 \quad (\text{anticommutator})$$

The usual notation $\{a,b\}_+$ cannot be used due to restrictions in the current language.

This domain only gives a Jordan algebra if the Jordan-identity

$$(a*b)*c + (b*c)*a + (c*a)*b = 0$$

holds for all a, b, c in A.

This relation can be checked by `jordanAdmissible?()$A`.

If the underlying algebra is of type `FramedNonAssociativeAlgebra(R)` (i.e. a non-associative algebra over R which is a free R-module of finite rank, together with a fixed R-module basis), then the same is true for the associated Jordan algebra. Moreover, if the underlying algebra is of type `FiniteRankNonAssociativeAlgebra(R)` (i.e. a non-associative algebra over R which is a free R-module of finite rank), then the same true for the associated Jordan algebra.

AssociatedLieAlgebra examples

=====

AssociatedLieAlgebra takes an algebra A and uses *\$A to define the Lie bracket

$a*b := (a * \$A b - b * \$A a)$ (commutator).

Note that the notation $[a,b]$ cannot be used due to restrictions of the current compiler. This domain only gives a Lie algebra if the Jacobi-identity

$$(a*b)*c + (b*c)*a + (c*a)*b = 0$$

holds for all a, b, c in A. This relation can be checked by `lieAdmissible?()$A`.

If the underlying algebra is of type `FramedNonAssociativeAlgebra(R)` (i.e. a non-associative algebra over R which is a free R-module of finite rank, together with a fixed R-module basis), then the same is true for the associated Lie algebra. Also, if the underlying algebra is of type `FiniteRankNonAssociativeAlgebra(R)` (i.e. a non-associative algebra over R which is a free R-module of finite rank), then the same is true for the associated Lie algebra.

++ Date Last Updated: 14 June 1991
++ Description:
++ AssociatedLieAlgebra takes an algebra \spad{A}
++ and uses \spadfun{*$A} to define the
++ Lie bracket \spad{a*b := (a *$A b - b *$A a)} (commutator). Note that

```

```

++ the notation \spad{[a,b]} cannot be used due to
++ restrictions of the current compiler.
++ This domain only gives a Lie algebra if the
++ Jacobi-identity \spad{(a*b)*c + (b*c)*a + (c*a)*b = 0} holds
++ for all \spad{a},\spad{b},\spad{c} in \spad{A}.
++ This relation can be checked by
++ \spad{lieAdmissible?()$A}.
++
++ If the underlying algebra is of type
++ \spadtype{FramedNonAssociativeAlgebra(R)} (i.e. a non
++ associative algebra over R which is a free \spad{R}-module of finite
++ rank, together with a fixed \spad{R}-module basis), then the same
++ is true for the associated Lie algebra.
++ Also, if the underlying algebra is of type
++ \spadtype{FiniteRankNonAssociativeAlgebra(R)} (i.e. a non
++ associative algebra over R which is a free R-module of finite
++ rank), then the same is true for the associated Lie algebra.

AssociatedLieAlgebra(R:CommutativeRing,A:NonAssociativeAlgebra R):
  public == private where
  public ==> Join (NonAssociativeAlgebra R, CoercibleTo A) with
    coerce : A -> %
      ++ coerce(a) coerces the element \spad{a} of the algebra \spad{A}
      ++ to an element of the Lie
      ++ algebra \spadtype{AssociatedLieAlgebra}(R,A).
  if A has FramedNonAssociativeAlgebra(R) then
    FramedNonAssociativeAlgebra(R)
  if A has FiniteRankNonAssociativeAlgebra(R) then
    FiniteRankNonAssociativeAlgebra(R)

private ==> A add
  Rep := A
  (a:%) * (b:%) == (a::Rep) * $Rep (b::Rep) - $Rep (b::Rep) * $Rep (a::Rep)

=====

AssociationList examples

=====

AssociationList implements association lists. These may be viewed as lists of pairs where the first part is a key and the second is the stored value. For example, the key might be a string with a persons employee identification number and the value might be a record with personnel data.

The AssociationList constructor provides a general structure for associative storage. This type provides association lists in which data objects can be saved according to keys of any type. For a given association list, specific types must be chosen for the keys and entries. You can think of the representation of an association list as a list of records with key and entry fields.

Association lists are a form of table and so most of the operations available for Table are also available for AssociationList. They can also be viewed as lists and can be manipulated accordingly.

This is a Record type with age and gender fields.

```

Data := Record(monthsOld : Integer, gender : String)
      Record(monthsOld: Integer,gender: String)
            Type: Domain

```

In this expression, al is declared to be an association list whose keys are strings and whose entries are the above records.

```

al : AssociationList(String,Data)
      Type: Void

```

The table operation is used to create an empty association list.

```

al := table()
table()
      Type: AssociationList(String,Record(monthsOld: Integer,gender: String))

```

You can use assignment syntax to add things to the association list.

```
al."bob" := [407,"male"]$Data
[monthsOld=407, gender= "male"]
      Type: Record(monthsOld: Integer,gender: String)

al."judith" := [366,"female"]$Data
[monthsOld=366, gender= "female"]
      Type: Record(monthsOld: Integer,gender: String)

al."katie" := [24,"female"]$Data
[monthsOld=24, gender= "female"]
      Type: Record(monthsOld: Integer,gender: String)
```

Perhaps we should have included a species field.

```
al."smokie" := [200,"female"]$Data
[monthsOld=200, gender= "female"]
      Type: Record(monthsOld: Integer,gender: String)
```

Now look at what is in the association list. Note that the last-added (key, entry) pair is at the beginning of the list.

```
al
table("smokie" = [monthsOld=200, gender= "female"],
      "katie" = [monthsOld=24, gender= "female"],
      "judith" = [monthsOld=366, gender= "female"],
      "bob" = [monthsOld=407, gender= "male"])
      Type: AssociationList(String,Record(monthsOld: Integer,gender: String))
```

You can reset the entry for an existing key.

```
al."katie" := [23,"female"]$Data
[monthsOld=23, gender= "female"]
      Type: Record(monthsOld: Integer,gender: String)
```

Use `delete!` to destructively remove an element of the association list. Use `delete` to return a copy of the association list with the element deleted. The second argument is the index of the element to delete.

```
delete!(al,1)
table("katie" = [monthsOld=23, gender= "female"],
      "judith" = [monthsOld=366, gender= "female"],
      "bob" = [monthsOld=407, gender= "male"])
      Type: AssociationList(String,Record(monthsOld: Integer,gender: String))
```

=====

AttributeButtons examples

=====

AttributeButtons implements a database and associated adjustment mechanisms for a set of attributes.

For ODEs these attributes are "stiffness", "stability" (i.e. how much affect the cosine or sine component of the solution has on the stability of the result), "accuracy" and "expense" (i.e. how expensive is the evaluation of the ODE). All these have bearing on the cost of calculating the solution given that reducing the step-length to achieve greater accuracy requires considerable number of evaluations and calculations.

The effect of each of these attributes can be altered by increasing or decreasing the button value.

For Integration there is a button for increasing and decreasing the preset number of function evaluations for each method. This is automatically used

by ANNA when a method fails due to insufficient workspace or where the limit of function evaluations has been reached before the required accuracy is achieved.

BalancedBinaryTree examples

=====

BalancedBinaryTree(S) is the domain of balanced binary trees (bbtree). A balanced binary tree of 2^k leaves, for some $k > 0$, is symmetric, that is, the left and right subtree of each interior node have identical shape. In general, the left and right subtree of a given node can differ by at most leaf node.

BalancedBinaryTrees(S) is the domain of balanced binary trees with elements of type S at the nodes. A binary tree is either empty or else consists of a node having a value and two branches, each branch a binary tree. A balanced binary tree is one that is balanced with respect its leaves. One with 2^k leaves is perfectly "balanced": the tree has minimum depth, and the left and right branch of every interior node is identical in shape.

Balanced binary trees are useful in algebraic computation for so-called "divide-and-conquer" algorithms. Conceptually, the data for a problem is initially placed at the root of the tree. The original data is then split into two subproblems, one for each subtree. And so on. Eventually, the problem is solved at the leaves of the tree. A solution to the original problem is obtained by some mechanism that can reassemble the pieces. In fact, an implementation of the Chinese Remainder Algorithm using balanced binary trees was first proposed by David Y. Y. Yun at the IBM T. J. Watson Research Center in Yorktown Heights, New York, in 1978. It served as the prototype for polymorphic algorithms in Axiom.

In what follows, rather than perform a series of computations with a single expression, the expression is reduced modulo a number of integer primes, a computation is done with modular arithmetic for each prime, and the Chinese Remainder Algorithm is used to obtain the answer to the original problem. We illustrate this principle with the

computation of $12^2 = 144$.

A list of moduli:

```
lm := [3,5,7,11]
      [3,5,7,11]
                                     Type: PositiveInteger
```

The expression `modTree(n, lm)` creates a balanced binary tree with leaf values $n \bmod m$ for each modulus m in `lm`.

```
modTree(12,lm)
[0, 2, 5, 1]
                                     Type: List Integer
```

Operation `modTree` does this using operations on balanced binary trees. We trace its steps. Create a balanced binary tree `t` of zeros with four leaves.

```
t := balancedBinaryTree(#lm, 0)
    [[0, 0, 0], 0, [0, 0, 0]]
                                     Type: BalancedBinaryTree NonNegativeInteger
```

The leaves of the tree are set to the individual moduli.

```
setleaves!(t,lm)
[[3, 0, 5], 0, [7, 0, 11]]
                                     Type: BalancedBinaryTree NonNegativeInteger
```

`mapUp!` to do a bottom-up traversal of `t`, setting each interior node to the product of the values at the nodes of its children.

```
mapUp!(t,_)
1155
                                     Type: PositiveInteger
```

The value at the node of every subtree is the product of the moduli of the leaves of the subtree.

```
t
[[3, 15, 5], 1155, [7, 77, 11]]
                                     Type: BalancedBinaryTree NonNegativeInteger
```

Operation `mapDown!(t,a,fn)` replaces the value `v` at each node of `t` by `fn(a,v)`.

```
mapDown!(t,12,_rem)
[[0, 12, 2], 12, [5, 12, 1]]
                                     Type: BalancedBinaryTree NonNegativeInteger
```

The operation `leaves` returns the leaves of the resulting tree. In this case, it returns the list of $12 \bmod m$ for each modulus m .

```
leaves %
[0, 2, 5, 1]
Type: List NonNegativeInteger
```

Compute the square of the images of 12 modulo each m .

```
squares := [x**2 rem m for x in % for m in lm]
[0, 4, 4, 1]
Type: List NonNegativeInteger
```

Call the Chinese Remainder Algorithm to get the answer for 12^2 .

```
chineseRemainder(%,lm)
144
Type: PositiveInteger
```

=====

BasicOperator examples

=====

A basic operator is an object that can be symbolically applied to a list of arguments from a set, the result being a kernel over that set or an expression.

You create an object of type BasicOperator by using the operator operation. This first form of this operation has one argument and it must be a symbol. The symbol should be quoted in case the name has been used as an identifier to which a value has been assigned.

A frequent application of BasicOperator is the creation of an operator to represent the unknown function when solving a differential equation.

Let y be the unknown function in terms of x .

```
y := operator 'y
y
Type: BasicOperator
```

This is how you enter the equation $y'' + y' + y = 0$.

```
deq := D(y x, x, 2) + D(y x, x) + y x = 0
''
y (x) + y (x) + y(x) = 0
Type: Equation Expression Integer
```

To solve the above equation, enter this.

```
solve(deq, y, x)
      x      x
    +-+  - -  - -  +-+
    x\|3  2    2    x\|3
[particular= 0,basis= [cos(----)%e  ,%e  sin(----)]]
                    2          2
Type: Union(Record(particular: Expression Integer,
                    basis: List Expression Integer),...)
```

Use the single argument form of BasicOperator (as above) when you intend to use the operator to create functional expressions with an arbitrary number of arguments

Nary means an arbitrary number of arguments can be used in the functional expressions.

```
nary? y
true
Type: Boolean
```

```
unary? y
false
Type: Boolean
```

Use the two-argument form when you want to restrict the number of arguments in the functional expressions created with the operator.

This operator can only be used to create functional expressions with one argument.

```
opOne := operator('opOne, 1)
opOne
```

Type: BasicOperator

```
nary? opOne
false
```

Type: Boolean

```
unary? opOne
true
```

Type: Boolean

Use `arity` to learn the number of arguments that can be used. It returns "false" if the operator is nary.

```
arity opOne
1
```

Type: Union(NonNegativeInteger,...)

Use `name` to learn the name of an operator.

```
name opOne
opOne
```

Type: Symbol

Use `is?` to learn if an operator has a particular name.

```
is?(opOne, 'z2)
false
```

Type: Boolean

You can also use a string as the name to be tested against.

```
is?(opOne, "opOne")
true
```

Type: Boolean

You can attach named properties to an operator. These are rarely used at the top-level of the Axiom interactive environment but are used with Axiom library source code.

By default, an operator has no properties.

```
properties y
table()
```

Type: AssociationList(String,None)

The interface for setting and getting properties is somewhat awkward because the property values are stored as values of type `None`.

Attach a property by using `setProperty`.

```
setProperty(y, "use", "unknown function" :: None )
y
```

Type: BasicOperator

```
properties y
table("use"=NONE)
```

Type: AssociationList(String, None)

We know the property value has type String.

```
property(y, "use") :: None pretend String
"unknown function"
```

Type: String

Use deleteProperty! to destructively remove a property.

```
deleteProperty!(y, "use")
y
```

Type: BasicOperator

```
properties y
table()
```

Type: AssociationList(String, None)

    ++ operator(f, n) makes f into an n-ary operator.
  arity : $ -> Union(NonNegativeInteger, "failed")
    ++ arity(op) returns n if op is n-ary, and
    ++ "failed" if op has arbitrary arity.
  nullary? : $ -> Boolean

```

```

    ++ nullary?(op) tests if op is nullary.
unary?    : $ -> Boolean
    ++ unary?(op) tests if op is unary.
nary?     : $ -> Boolean
    ++ nary?(op) tests if op has arbitrary arity.
weight    : $ -> NonNegativeInteger
    ++ weight(op) returns the weight attached to op.
weight    : ($, NonNegativeInteger) -> $
    ++ weight(op, n) attaches the weight n to op.
equality   : ($, ($, $) -> Boolean) -> $
    ++ equality(op, foo?) attaches foo? as the "%equal?" property
    ++ to op. If op1 and op2 have the same name, and one of them
    ++ has an "%equal?" property f, then \spad{f(op1, op2)} is called to
    ++ decide whether op1 and op2 should be considered equal.
comparison : ($, ($, $) -> Boolean) -> $
    ++ comparison(op, foo?) attaches foo? as the "%less?" property
    ++ to op. If op1 and op2 have the same name, and one of them
    ++ has a "%less?" property f, then \spad{f(op1, op2)} is called to
    ++ decide whether \spad{op1 < op2}.
display    : $ -> Union(List 0 -> 0, "failed")
    ++ display(op) returns the "%display" property of op if
    ++ it has one attached, and "failed" otherwise.
display    : ($, List 0 -> 0) -> $
    ++ display(op, foo) attaches foo as the "%display" property
    ++ of op. If op has a "%display" property f, then \spad{op(a1,...,an)}
    ++ gets converted to OutputForm as \spad{f(a1,...,an)}.
display    : ($, 0 -> 0) -> $
    ++ display(op, foo) attaches foo as the "%display" property
    ++ of op. If op has a "%display" property f, then \spad{op(a)}
    ++ gets converted to OutputForm as \spad{f(a)}.
    ++ Argument op must be unary.
input      : ($, List SEX -> SEX) -> $
    ++ input(op, foo) attaches foo as the "%input" property
    ++ of op. If op has a "%input" property f, then \spad{op(a1,...,an)}
    ++ gets converted to InputForm as \spad{f(a1,...,an)}.
input      : $ -> Union(List SEX -> SEX, "failed")
    ++ input(op) returns the "%input" property of op if
    ++ it has one attached, "failed" otherwise.
is?        : ($, Symbol) -> Boolean
    ++ is?(op, s) tests if the name of op is s.
has?       : ($, String) -> Boolean
    ++ has?(op, s) tests if property s is attached to op.
assert     : ($, String) -> $
    ++ assert(op, s) attaches property s to op.
    ++ Argument op is modified "in place", i.e. no copy is made.
deleteProperty_! : ($, String) -> $
    ++ deleteProperty!(op, s) unattaches property s from op.
    ++ Argument op is modified "in place", i.e. no copy is made.
property    : ($, String) -> Union(None, "failed")
    ++ property(op, s) returns the value of property s if

```

```

    ++ it is attached to op, and "failed" otherwise.
setProperty : ($, String, None) -> $
    ++ setProperty(op, s, v) attaches property s to op,
    ++ and sets its value to v.
    ++ Argument op is modified "in place", i.e. no copy is made.
setProperty : ($, P) -> $
    ++ setProperties(op, l) sets the property list of op to l.
    ++ Argument op is modified "in place", i.e. no copy is made.

=====
BasicStochasticDifferential examples
=====

```

Based on Symbol: a domain of symbols representing basic stochastic differentials, used in StochasticDifferential(R) in the underlying sparse multivariate polynomial representation.

We create new BSD only by coercion from Symbol using a special function introduce! first of all to add to a private set SDset. We allow a separate function convertIfCan which will check whether the argument has previously been declared as a BSD.

The copyBSD() returns setBSD as a list of BSD.

Initially the BSD table of symbols is empty:

```

print copyBSD()
[]

```

as is the Ito table. The copyIto() returns the table relating semimartingales to basic stochastic differentials.

```
print copyIto()
      table()
```

We introduce a new stochastic differential:

```
dX:=introduce!(X,dX) -- dX is a new stochastic differential
      dX
```

and now it is in the BSD table of symbols:

```
print copyBSD()
      [dX]
```

and the Ito table:

```
print copyIto()
      table(X= dX)
```

The `getSmgl(bsd)` returns the semimartingale S related to the basic stochastic differential `bsd` by `introduce!`:

```
getSmgl(dX)
      X
```

Note that the `dX` symbol is of type `BasicStochasticDifferential`:

```
print domainOf(dX)
      BasicStochasticDifferential()
```

The `d` function, `d(X)` returns `dX` if `tableIto(X)=dX` otherwise 0:

```
print d X
      dX
```

and we can specify the domain:

```
print ((d$BSD) X)
      dX
```

which clearly is of domain `BasicStochasticDifferential`

```
print domainOf((d$BSD) X)
      BasicStochasticDifferential()
```

The `introduce!(X,dX)` returns `dX` as BSD if it isn't already in BSD

```
introduce!(t,dt) -- dt is a new stochastic differential
      dt
```

Now we can see that `dt` is in the BSD table:

```
print copyBSD()
      [dX,dt]
```

and the Ito table:

```
print copyIto()
      table(t= dt,X= dX)
```

You cannot repeat an `introduce!` for an existing entry:

```
introduce!(t,dt)
"failed"
```

Regular symbols can be added, especially with subscripts:

```
[introduce!(A[i],dA[i]) for i in 1..2]
      [dA1,dA2]
```

And we can see them in the BSD table:

```
print copyBSD()
      [dA1,dA2,dX,dt]
```

and the Ito table:

```
print copyIto()
      table(A = dA2, A = dA2, t= dt, X= dX1)
```

The d function can extract these symbols:

```
[d A[i] for i in 1..2]
      [dA1,dA2]
```

)abbrev domain BSD BasicStochasticDifferential
++ Author: Wilfrid S. Kendall
++ Date Last Updated: July 26, 1999
++ Related Domains: StochasticDifferential(R)
++ References: Ito (1975), Kendall (1991a,b; 1993a,b; 1999a,b).
++ Description:
++ Based on Symbol: a domain of symbols representing basic stochastic
++ differentials, used in StochasticDifferential(R) in the underlying
++ sparse multivariate polynomial representation.
++
++ We create new BSD only by coercion from Symbol using a special
++ function introduce! first of all to add to a private set SDset.
++ We allow a separate function convertIfCan which will check whether the
++ argument has previously been declared as a BSD.

BasicStochasticDifferential(): category == implementation where
  INT ==> Integer
  OF ==> OutputForm
  category ==> OrderedSet with
    ConvertibleTo(Symbol)

  convertIfCan: Symbol -> Union(%, "failed")
    ++ convertIfCan(ds) transforms \axiom{dX} into a \axiom{BSD}
    ++ if possible (if \axiom{introduce(X,dX)} has
    ++ been invoked previously).

  convert: Symbol -> %
    ++ convert(dX) transforms \axiom{dX} into a \axiom{BSD}
    ++ if possible and otherwise produces an error.

  introduce!: (Symbol,Symbol) -> Union(%, "failed")
    ++ introduce!(X,dX) returns \axiom{dX} as \axiom{BSD} if it
    ++ isn't already in \axiom{BSD}
    ++
    ++X introduce!(t,dt) -- dt is a new stochastic differential
    ++X copyBSD()

  d: Symbol -> Union(%,INT)
    ++ d(X) returns \axiom{dX} if \axiom{tableIto(X)=dX}
    ++ and otherwise returns \axiom{0}

  copyBSD:() -> List %

```

```

++ copyBSD() returns \axiom{setBSD} as a list of \axiom{BSD}.
++
++X introduce!(t,dt) -- dt is a new stochastic differential
++X copyBSD()

copyIto:() -> Table(Symbol,%)
++ copyIto() returns the table relating semimartingales
++ to basic stochastic differentials.
++
++X introduce!(t,dt) -- dt is a new stochastic differential
++X copyIto()

BinaryExpansion examples

=====

All rational numbers have repeating binary expansions. Operations to access the individual bits of a binary expansion can be obtained by converting the value to RadixExpansion(2). More examples of expansions are available with

The expansion (of type BinaryExpansion) of a rational number is returned by the binary operation.

```

r := binary(22/7)
--
11.001
Type: BinaryExpansion

```

Arithmetic is exact.

```

r + binary(6/7)
100
Type: BinaryExpansion

```

The period of the expansion can be short or long.

```

[binary(1/i) for i in 102..106]
-----
[0.00000101,
-----
0.000000100111110001000101100101111001110010010101001,
-----
0.000000100111011, 0.000000100111,
-----
0.00000010011010100100001110011111011001010110111100011]
Type: List BinaryExpansion

```

or very long.

```

binary(1/1007)
-----
0.000000000100000100010100100101111000001111110000101111110010110001111101

— BinarySearchTree.help —

```
=====
BinarySearchTree examples
=====
```

BinarySearchTree(R) is the domain of binary trees with elements of type R, ordered across the nodes of the tree. A non-empty binary search tree has a value of type R, and right and left binary search subtrees. If a subtree is empty, it is displayed as a period (".").

Define a list of values to be placed across the tree. The resulting tree has 8 at the root; all other elements are in the left subtree.

```
lv := [8,3,5,4,6,2,1,5,7]
      [8, 3, 5, 4, 6, 2, 1, 5, 7]
                                     Type: List PositiveInteger
```

A convenient way to create a binary search tree is to apply the operation binarySearchTree to a list of elements.

```
t := binarySearchTree lv
    [[[1, 2, .], 3, [4, 5, [5, 6, 7]]], 8, .]
                                     Type: BinarySearchTree PositiveInteger
```

Another approach is to first create an empty binary search tree of integers.

```
emptybst := empty()$BSTREE(INT)
[]
                                     Type: BinarySearchTree Integer
```

Insert the value 8. This establishes 8 as the root of the binary search tree. Values inserted later that are less than 8 get stored in the left subtree, others in the right subtree.

```
t1 := insert!(8,emptybst)
      8
                                     Type: BinarySearchTree Integer
```

Insert the value 3. This number becomes the root of the left subtree of t1. For optimal retrieval, it is thus important to insert the middle elements first.

```
insert!(3,t1)
      [3, 8, .]
                                     Type: BinarySearchTree Integer
```

We go back to the original tree t. The leaves of the binary search tree are those which have empty left and right subtrees.

```

leaves t
[1, 4, 5, 7]
Type: List PositiveInteger

```

The operation `split(k,t)` returns a record containing the two subtrees: one with all elements "less" than `k`, another with elements "greater" than `k`.

```

split(3,t)
[less=[1, 2, .], greater=[[., 3, [4, 5, [5, 6, 7]]], 8, .]]
Type: Record(less: BinarySearchTree PositiveInteger,greater:
BinarySearchTree PositiveInteger)

```

Define `insertRoot` to insert new elements by creating a new node.

```

insertRoot: (INT,BSTREE INT) -> BSTREE INT
Type: Void

```

The new node puts the inserted value between its "less" tree and "greater" tree.

```

insertRoot(x, t) ==
a := split(x, t)
node(a.less, x, a.greater)
Type: Void

```

Function `buildFromRoot` builds a binary search tree from a list of elements `ls` and the empty tree `emptybst`.

```

buildFromRoot ls == reduce(insertRoot,ls,emptybst)
Type: Void

```

Apply this to the reverse of the list `lv`.

```

rt := buildFromRoot reverse lv
[[[1, 2, . ], 3, [4, 5, [5, 6, 7]]], 8, .]
Type: BinarySearchTree Integer

```

Have Axiom check that these are equal.

```

(t = rt)@Boolean
true
Type: Boolean

```

=====
CardinalNumber examples
=====

```

The CardinalNumber domain can be used for values indicating the cardinality of sets, both finite and infinite. For example, the dimension operation in the category VectorSpace returns a cardinal number.

The non-negative integers have a natural construction as cardinals

$$0 = \#\{ \}, 1 = \{0\}, 2 = \{0, 1\}, \dots, n = \{i \mid 0 \leq i < n\}.$$

The fact that 0 acts as a zero for the multiplication of cardinals is equivalent to the axiom of choice.

Cardinal numbers can be created by conversion from non-negative integers.

```
c0 := 0 :: CardinalNumber
0
                                Type: CardinalNumber

c1 := 1 :: CardinalNumber
1
                                Type: CardinalNumber

c2 := 2 :: CardinalNumber
2
                                Type: CardinalNumber

c3 := 3 :: CardinalNumber
3
                                Type: CardinalNumber
```

They can also be obtained as the named cardinal Aleph(n).

```
A0 := Aleph 0
Aleph(0)
                                Type: CardinalNumber

A1 := Aleph 1
Aleph(1)
                                Type: CardinalNumber
```

The finite? operation tests whether a value is a finite cardinal, that is, a non-negative integer.

```
finite? c2
true
                                Type: Boolean

finite? A0
false
                                Type: Boolean
```

Similarly, the `countable?` operation determines whether a value is a countable cardinal, that is, finite or $\text{Aleph}(0)$.

```
countable? c2
true
Type: Boolean
```

```
countable? A0
true
Type: Boolean
```

```
countable? A1
false
Type: Boolean
```

Arithmetic operations are defined on cardinal numbers as follows:
If $x = \#X$ and $y = \#Y$ then

```
x+y = #(X+Y) cardinality of the disjoint union
x-y = #(X-Y) cardinality of the relative complement
x*y = #(X*Y) cardinality of the Cartesian product
x**y = #(X**Y) cardinality of the set of maps from Y to X
```

Here are some arithmetic examples.

```
[c2 + c2, c2 + A1]
[4, Aleph(1)]
Type: List CardinalNumber
```

```
[c0*c2, c1*c2, c2*c2, c0*A1, c1*A1, c2*A1, A0*A1]
[0, 2, 4, 0, Aleph(1), Aleph(1), Aleph(1)]
Type: List CardinalNumber
```

```
[c2**c0, c2**c1, c2**c2, A1**c0, A1**c1, A1**c2]
[1, 2, 4, 1, Aleph(1), Aleph(1)]
Type: List CardinalNumber
```

Subtraction is a partial operation: it is not defined when subtracting a larger cardinal from a smaller one, nor when subtracting two equal infinite cardinals.

```
[c2-c1, c2-c2, c2-c3, A1-c2, A1-A0, A1-A1]
[1, 0, "failed", Aleph(1), Aleph(1), "failed"]
Type: List Union(CardinalNumber,"failed")
```

The generalized continuum hypothesis asserts that

```
2**Aleph i = Aleph(i+1)
```

and is independent of the axioms of set theory.

(reference: Goedel, The consistency of the continuum hypothesis,
Ann. Math. Studies, Princeton Univ. Press, 1940.)

The CardinalNumber domain provides an operation to assert whether the hypothesis is to be assumed.

```
generalizedContinuumHypothesisAssumed true
true
```

Type: Boolean

When the generalized continuum hypothesis is assumed, exponentiation to a transfinite power is allowed.

```
[c0**A0, c1**A0, c2**A0, A0**A0, A0**A1, A1**A0, A1**A1]
[0, 1, Aleph(1), Aleph(1), Aleph(2), Aleph(1), Aleph(2)]
Type: List CardinalNumber
```

Three commonly encountered cardinal numbers are

```
a = #Z countable infinity
c = #R the continuum
f = #{g| g: [0,1] -> R}
```

In this domain, these values are obtained under the generalized continuum hypothesis in this way.

```
a := Aleph 0
Aleph(0)
```

Type: CardinalNumber

```
c := 2**a
Aleph(1)
```

Type: CardinalNumber

```
f := 2**c
Aleph(2)
```

Type: CardinalNumber

=====
 CartesianTensor examples
 =====

CartesianTensor(i0,dim,R) provides Cartesian tensors with components belonging to a commutative ring R. Tensors can be described as a generalization of vectors and matrices. This gives a concise tensor algebra for multilinear objects supported by the CartesianTensor domain. You can form the inner or outer product of any two tensors and you can add or subtract tensors with the same number of components. Additionally, various forms of traces and transpositions are useful.

The CartesianTensor constructor allows you to specify the minimum index for subscripting. In what follows we discuss in detail how to manipulate tensors.

Here we construct the domain of Cartesian tensors of dimension 2 over the integers, with indices starting at 1.

```
CT := CARTEN(i0 := 1, 2, Integer)
      CartesianTensor(1,2,Integer)
                        Type: Domain
```

=====
 Forming tensors
 =====

Scalars can be converted to tensors of rank zero.

```
t0: CT := 8
      8
                        Type: CartesianTensor(1,2,Integer)

rank t0
      0
                        Type: NonNegativeInteger
```

Vectors (mathematical direct products, rather than one dimensional array structures) can be converted to tensors of rank one.

```
v: DirectProduct(2, Integer) := directProduct [3,4]
      [3, 4]
```

Type: DirectProduct(2,Integer)

Tv: CT := v
[3, 4]

Type: CartesianTensor(1,2,Integer)

Matrices can be converted to tensors of rank two.

m: SquareMatrix(2, Integer) := matrix [[1,2],[4,5]]
+1 2+
| |
+4 5+

Type: SquareMatrix(2,Integer)

Tm: CT := m
+1 2+
| |
+4 5+

Type: CartesianTensor(1,2,Integer)

n: SquareMatrix(2, Integer) := matrix [[2,3],[0,1]]
+2 3+
| |
+0 1+

Type: SquareMatrix(2,Integer)

Tn: CT := n
+2 3+
| |
+0 1+

Type: CartesianTensor(1,2,Integer)

In general, a tensor of rank k can be formed by making a list of rank k-1 tensors or, alternatively, a k-deep nested list of lists.

t1: CT := [2, 3]
[2, 3]

Type: CartesianTensor(1,2,Integer)

rank t1
1

Type: PositiveInteger

t2: CT := [t1, t1]
+2 3+
| |
+2 3+

Type: CartesianTensor(1,2,Integer)

t3: CT := [t2, t2]

```

+2  3+ +2  3+
[|   |,|   |]
+2  3+ +2  3+
Type: CartesianTensor(1,2,Integer)

```

```

tt: CT := [t3, t3]; tt := [tt, tt]
++2  3+ +2  3++ ++2  3+ +2  3++
||   | |   || ||   | |   ||
|+2  3+ +2  3+| |+2  3+ +2  3+|
[|   |,|   |]
|+2  3+ +2  3+| |+2  3+ +2  3+|
||   | |   || ||   | |   ||
++2  3+ +2  3++ ++2  3+ +2  3++
Type: CartesianTensor(1,2,Integer)

```

```

rank tt
5
Type: PositiveInteger

```

Multiplication

Given two tensors of rank k_1 and k_2 , the outer product forms a new tensor of rank k_1+k_2 . Here

```

Tmn(i,j,k,l) = Tm(i,j)Tn(k,l)

Tmn := product(Tm, Tn)
++2  3+   +4  6+ +
||   |   |   ||
|+0  1+   +0  2+ |
|   |   |   |
|+8  12+ +10  15+|
||   |   |   ||
++0  4 +   +0  5 ++
Type: CartesianTensor(1,2,Integer)

```

The inner product (contract) forms a tensor of rank k_1+k_2-2 . This product generalizes the vector dot product and matrix-vector product by summing component products along two indices.

Here we sum along the second index of T_m and the first index of T_v . Here

```

Tmv = sum {j=1..dim} Tm(i,j) Tv(j)

Tmv := contract(Tm,2,Tv,1)
[11,32]
Type: CartesianTensor(1,2,Integer)

```

The multiplication operator `*` is scalar multiplication or an inner product depending on the ranks of the arguments.

If either argument is rank zero it is treated as scalar multiplication. Otherwise, `a*b` is the inner product summing the last index of `a` with the first index of `b`.

```
Tm*Tv
[11,32]
Type: CartesianTensor(1,2,Integer)
```

This definition is consistent with the inner product on matrices and vectors.

```
Tmv = m * v
[11,32] = [11,32]
Type: Equation CartesianTensor(1,2,Integer)
```

```
=====
Selecting Components
=====
```

For tensors of low rank (that is, four or less), components can be selected by applying the tensor to its indices.

```
t0()
8
Type: PositiveInteger

t1(1+1)
3
Type: PositiveInteger

t2(2,1)
2
Type: PositiveInteger

t3(2,1,2)
3
Type: PositiveInteger

Tmn(2,1,2,1)
0
Type: NonNegativeInteger
```

A general indexing mechanism is provided for a list of indices.

```
t0[]
8
```

Type: PositiveInteger

```
t1[2]
  3
```

Type: PositiveInteger

```
t2[2,1]
  2
```

Type: PositiveInteger

The general mechanism works for tensors of arbitrary rank, but is somewhat less efficient since the intermediate index list must be created.

```
t3[2,1,2]
  3
```

Type: PositiveInteger

```
Tmn[2,1,2,1]
  0
```

Type: NonNegativeInteger

```
=====
Contraction
=====
```

A "contraction" between two tensors is an inner product, as we have seen above. You can also contract a pair of indices of a single tensor. This corresponds to a "trace" in linear algebra. The expression `contract(t,k1,k2)` forms a new tensor by summing the diagonal given by indices in position `k1` and `k2`.

This is the tensor given by

```
xTmn = sum{k=1..dim} Tmn(k,k,i,j)
```

```
cTmn := contract(Tmn,1,2)
+12 18+
|    |
+0  6 +
```

Type: CartesianTensor(1,2,Integer)

Since `Tmn` is the outer product of matrix `m` and matrix `n`, the above is equivalent to this.

```
trace(m) * n
+12 18+
|    |
+0  6 +
```

Type: SquareMatrix(2,Integer)

In this and the next few examples, we show all possible contractions

of T_{mn} and their matrix algebra equivalents.

```
contract(Tmn,1,2) = trace(m) * n
+12 18+ +12 18+
|      |= |      |
+0   6+ +0   6+
Type: Equation CartesianTensor(1,2,Integer)
```

```
contract(Tmn,1,3) = transpose(m) * n
+2  7+ +2  7+
|      |= |      |
+4 11+ +4 11+
Type: Equation CartesianTensor(1,2,Integer)
```

```
contract(Tmn,1,4) = transpose(m) * transpose(n)
+14 4+ +14 4+
|      |= |      |
+19 5+ +19 5+
Type: Equation CartesianTensor(1,2,Integer)
```

```
contract(Tmn,2,3) = m * n
+2  5+ +2  5+
|      |= |      |
+8 17+ +8 17+
Type: Equation CartesianTensor(1,2,Integer)
```

```
contract(Tmn,2,4) = m * transpose(n)
+8  2+ +8  2+
|      |= |      |
+23 5+ +23 5+
Type: Equation CartesianTensor(1,2,Integer)
```

```
contract(Tmn,3,4) = trace(n) * m
+3  6+ +3  6+
|      |= |      |
+12 15+ +12 15+
Type: Equation CartesianTensor(1,2,Integer)
```

Transpositions

You can exchange any desired pair of indices using the transpose operation.

Here the indices in positions one and three are exchanged, that is,
 $tTmn(i,j,k,l) = Tmn(k,j,i,l)$

```
tTmn := transpose(Tmn,1,3)
++2  3+ ++4  6++
```

```

||      |  |      ||
|+8  12+  +10  15+|
|      |      |
|+0  1+    +0  2+ |
||      |  |      ||
++0  4+    +0  5+ +

```

Type: CartesianTensor(1,2,Integer)

If no indices are specified, the first and last index are exchanged.

```

transpose Tmn
++2  8+  +4  10++
||      |  |      ||
|+0  0+  +0  0 +|
|      |      |
|+3  12+  +6  15+|
||      |  |      ||
++1  4 +  +2  5 ++

```

Type: CartesianTensor(1,2,Integer)

This is consistent with the matrix transpose.

```

transpose Tm = transpose m
+1  4+  +1  4+
|      | = |      |
+2  5+  +2  5+

```

Type: Equation CartesianTensor(1,2,Integer)

If a more complicated reordering of the indices is required, then the `reindex` operation can be used. This operation allows the indices to be arbitrarily permuted.

```

rTmn(i,j,k,l) = Tmn(i,l,j,k)

```

```

rTmn := reindex(Tmn, [1,4,2,3])

```

```

++2  0+  +3  1+ +
||      |  |      ||
|+4  0+  +6  2+ |
|      |      |
|+8  0+  +12  4+|
||      |  |      ||
++10  0+  +15  5++

```

Type: CartesianTensor(1,2,Integer)

Arithmetic

Tensors of equal rank can be added or subtracted so arithmetic

expressions can be used to produce new tensors.

```
tt := transpose(Tm)*Tn - Tn*transpose(Tm)
+- 6 - 16+
|      |
+ 2    6 +
Type: CartesianTensor(1,2,Integer)
```

```
Tv*(tt+Tn)
[- 4,- 11]
Type: CartesianTensor(1,2,Integer)
```

```
reindex(product(Tn,Tn),[4,3,2,1])+3*Tn*product(Tm,Tm)
++46 84 + +57 114++
||      | |      ||
|+174 212+ +228 285+|
|      |
| +18 24+ +17 30+ |
| |      | |      |
+ +57 63+ +63 76+ +
Type: CartesianTensor(1,2,Integer)
```

Specific Tensors

Two specific tensors have properties which depend only on the dimension.

The Kronecker delta satisfies

$$\text{delta}(i,j) = \begin{array}{cc} \begin{array}{c} +- \\ | \\ +- \end{array} & \begin{array}{c} 1 \text{ if } i = j \\ 0 \text{ if } i \neq j \end{array} & \begin{array}{c} -+ \\ | \\ -+ \end{array} \end{array}$$

```
delta: CT := kroneckerDelta()
+1 0+
|   |
+0 1+
Type: CartesianTensor(1,2,Integer)
```

This can be used to reindex via contraction.

```
contract(Tmn, 2, delta, 1) = reindex(Tmn, [1,3,4,2])
+ +2 4+ +0 0++ + +2 4+ +0 0++
| |      | |      | |      | |
| +3 6+ +1 2+| | +3 6+ +1 2+|
```

```

      |      |      |      | | | | | | | | |
      |+8    10+   +0   0+|  |+8    10+   +0   0+|
      ||      |   |   ||   ||      |   |   ||
      ++12   15+  +4   5++  ++12   15+  +4   5++
                                Type: Equation CartesianTensor(1,2,Integer)

```

The Levi Civita symbol determines the sign of a permutation of indices.

```

epsilon:CT := leviCivitaSymbol()
+ 0      1+
|         |
+- 1      0+
                                Type: CartesianTensor(1,2,Integer)

```

Here we have:

```

epsilon(i1,...,idim)
= +1 if i1,...,idim is an even permutation of i0,...,i0+dim-1
= -1 if i1,...,idim is an odd permutation of i0,...,i0+dim-1
= 0 if i1,...,idim is not a permutation of i0,...,i0+dim-1

```

This property can be used to form determinants.

```

contract(epsilon*Tm*epsilon, 1,2) = 2 * determinant m
- 6= - 6
                                Type: Equation CartesianTensor(1,2,Integer)

```

Properties of the CartesianTensor domain

`GradedModule(R,E)` denotes "E-graded R-module", that is, a collection of R-modules indexed by an abelian monoid E. An element g of $G[s]$ for some specific s in E is said to be an element of G with degree s . Sums are defined in each module $G[s]$ so two elements of G can be added if they have the same degree. Morphisms can be defined and composed by degree to give the mathematical category of graded modules.

`GradedAlgebra(R,E)` denotes "E-graded R-algebra". A graded algebra is a graded module together with a degree preserving R-bilinear map, called the product.

```

degree(product(a,b))    = degree(a) + degree(b)

product(r*a,b)          = product(a,r*b) = r*product(a,b)
product(a1+a2,b)        = product(a1,b) + product(a2,b)
product(a,b1+b2)         = product(a,b1) + product(a,b2)
product(a,product(b,c)) = product(product(a,b),c)

```

The domain `CartesianTensor(i0, dim, R)` belongs to the category `GradedAlgebra(R, NonNegativeInteger)`. The non-negative integer degree is the tensor rank and the graded algebra product is the tensor outer product. The graded module addition captures the notion that only tensors of equal rank can be added.

If V is a vector space of dimension dim over R , then the tensor module $T[k](V)$ is defined as

$$\begin{aligned} T[0](V) &= R \\ T[k](V) &= T[k-1](V) * V \end{aligned}$$

where $*$ denotes the R -module tensor product. `CartesianTensor(i0,dim,R)` is the graded algebra in which the degree k module is $T[k](V)$.

Tensor Calculus

It should be noted here that often tensors are used in the context of tensor-valued manifold maps. This leads to the notion of covariant and contravariant bases with tensor component functions transforming in specific ways under a change of coordinates on the manifold. This is no more directly supported by the `CartesianTensor` domain than it is by the `Vector` domain. However, it is possible to have the components implicitly represent component maps by choosing a polynomial or expression type for the components. In this case, it is up to the user to satisfy any constraints which arise on the basis of this interpretation.

)abbrev domain CARTEN CartesianTensor
++ Author: Stephen M. Watt
++ Date Created: December 1986
++ Date Last Updated: May 15, 1991
++ Description:
++ CartesianTensor(minix,dim,R) provides Cartesian tensors with
++ components belonging to a commutative ring R. These tensors
++ can have any number of indices. Each index takes values from
++ \spad{minix} to \spad{minix + dim - 1}.

```
=====
Character examples
=====
```

The members of the domain Character are values representing letters, numerals and other text elements.

Characters can be obtained using String notation.

```
chars := [char "a", char "A", char "X", char "8", char "+"]
[a,A,X,8,+]
```

Type: List Character

Certain characters are available by name. This is the blank character.

```
space()
```

Type: Character

This is the quote that is used in strings.

```
quote()
"
```

Type: Character

This is the escape character that allows quotes and other characters within strings.

```
escape()
```

```
-
```

Type: Character

Characters are represented as integers in a machine-dependent way. The integer value can be obtained using the ord operation. It is always true that char(ord c) = c and ord(char i) = i, provided that i is in the range 0..size()\$Character-1.

```
[ord c for c in chars]
[97,65,88,56,43]
```

Type: List Integer

The `lowerCase` operation converts an upper case letter to the corresponding lower case letter. If the argument is not an upper case letter, then it is returned unchanged.

```
[upperCase c for c in chars]
[A,A,X,8,+]
Type: List Character
```

The `upperCase` operation converts lower case letters to upper case.

```
[lowerCase c for c in chars]
[a,a,x,8,+]
Type: List Character
```

A number of tests are available to determine whether characters belong to certain families.

```
[alphabetic? c for c in chars]
[true,true,true,false,false]
Type: List Boolean
```

```
[upperCase? c for c in chars]
[false,true,true,false,false]
Type: List Boolean
```

```
[lowerCase? c for c in chars]
[true,false,false,false,false]
Type: List Boolean
```

```
[digit? c for c in chars]
[false,false,false,true,false]
Type: List Boolean
```

```
[hexDigit? c for c in chars]
[true,true,false,true,false]
Type: List Boolean
```

```
[alphanumeric? c for c in chars]
[true,true,true,true,false]
Type: List Boolean
```

— domain CHAR Character —

```

)abbrev domain CHAR Character
++ Author: Stephen M. Watt
++ Date Created: July 1986
++ Date Last Updated: June 20, 1991
++ Description:
++ This domain provides the basic character data type.

```

```

Character: OrderedFinite() with
ord: % -> Integer
  ++ord(c) provides an integral code corresponding to the
  ++character c. It is always true that \spad{char ord c = c}.
  ++
  ++X chars := [char "a", char "A", char "X", char "8", char "+"]
  ++X [ord c for c in chars]
char: Integer -> %
  ++char(i) provides a character corresponding to the integer
  ++code i. It is always true that \spad{ord char i = i}.
  ++
  ++X [char c for c in [97,65,88,56,43]]
char: String -> %

```

```

++char(s) provides a character from a string s of length one.
++
++X [char c for c in ["a","A","X","8","+"]]
space: () -> %
++space() provides the blank character.
++
++X space()
quote: () -> %
++quote() provides the string quote character, \spad{".
++
++X quote()
escape: () -> %
++escape() provides the escape character, \spad{_, which
++is used to allow quotes and other characters within strings.
++
++X escape()
upperCase: % -> %
++upperCase(c) converts a lower case letter to the corresponding
++upper case letter. If c is not a lower case letter, then
++it is returned unchanged.
++
++X chars := [char "a", char "A", char "X", char "8", char "+"]
++X [upperCase c for c in chars]
lowerCase: % -> %
++lowerCase(c) converts an upper case letter to the corresponding
++lower case letter. If c is not an upper case letter, then
++it is returned unchanged.
++
++X chars := [char "a", char "A", char "X", char "8", char "+"]
++X [lowerCase c for c in chars]
digit?: % -> Boolean
++digit?(c) tests if c is a digit character, for example, one of 0..9.
++
++X chars := [char "a", char "A", char "X", char "8", char "+"]
++X [digit? c for c in chars]
hexDigit?: % -> Boolean
++hexDigit?(c) tests if c is a hexadecimal numeral,
++for example, one of 0..9, a..f or A..F.
++
++X chars := [char "a", char "A", char "X", char "8", char "+"]
++X [hexDigit? c for c in chars]
alphabetic?: % -> Boolean
++alphabetic?(c) tests if c is a letter,
++for example, one of a..z or A..Z.
++
++X chars := [char "a", char "A", char "X", char "8", char "+"]
++X [alphabetic? c for c in chars]
upperCase?: % -> Boolean
++upperCase?(c) tests if c is an upper case letter,
++for example, one of A..Z.

```

```

++
++X chars := [char "a", char "A", char "X", char "8", char "+"]
++X [upperCase? c for c in chars]
lowerCase?: % -> Boolean
++lowerCase?(c) tests if c is an lower case letter,
++for example, one of a..z.
++
++X chars := [char "a", char "A", char "X", char "8", char "+"]
++X [lowerCase? c for c in chars]
alphanumeric?: % -> Boolean
++alphanumeric?(c) tests if c is either a letter or number,
++for example, one of 0..9, a..z or A..Z.
++
++X chars := [char "a", char "A", char "X", char "8", char "+"]

)abbrev domain CCLASS CharacterClass
++ Author: Stephen M. Watt
++ Date Created: July 1986
++ Date Last Updated: June 20, 1991
++ Description:
++ This domain allows classes of characters to be defined and manipulated
++ efficiently.

```

```

CharacterClass: Join(SetCategory, ConvertibleTo String,
  FiniteSetAggregate Character, ConvertibleTo List Character) with
  charClass: String -> %
    ++ charClass(s) creates a character class which contains
    ++ exactly the characters given in the string s.
  charClass: List Character -> %
    ++ charClass(l) creates a character class which contains
    ++ exactly the characters given in the list l.
  digit: constant -> %
    ++ digit() returns the class of all characters
    ++ for which digit? is true.
  hexDigit: constant -> %
    ++ hexDigit() returns the class of all characters for which
    ++ hexDigit? is true.
  upperCase: constant -> %
    ++ upperCase() returns the class of all characters for which
    ++ upperCase? is true.
  lowerCase: constant -> %
    ++ lowerCase() returns the class of all characters for which
    ++ lowerCase? is true.
  alphabetic : constant -> %
    ++ alphabetic() returns the class of all characters for which
    ++ alphabetic? is true.

```

domain CLIF CliffordAlgebra[?, ?]

Vector (linear) spaces

This information is originally from Paul Leopardi's presentation on the *Introduction to Clifford Algebras* and is included here as an outline with his permission. Further details are based on the book by Doran and Lasenby called *Geometric Algebra for Physicists*.

Consider the various kinds of products that can occur between vectors. There are scalar and vector products from 3D geometry. There are the complex and quaterion products. There is also the *outer* or *exterior* product.

Vector addition commutes:

$$a + b = b + a$$

Vector addition is associative:

$$a + (b + c) = (a + b) + c$$

The identity vector exists:

$$a + 0 = a$$

Every vector has an inverse:

$$a + (-a) = 0$$

If we consider vectors to be directed line segments, thus establishing a geometric meaning for a vector, then each of these properties has a geometric meaning.

A multiplication operator exists between scalars and vectors with the properties:

$$\lambda(a + b) = \lambda a + \lambda b$$

$$(\lambda + \mu)a = \lambda a + \mu a$$

$$(\lambda\mu)a = \lambda(\mu a)$$

If $1\lambda = \lambda$ for all scalars λ then $1a = a$ for all vectors a

These properties completely define a vector (linear) space. The $+$ operation for scalar arithmetic is not the same as the $+$ operation for vectors.

Definition: Isomorphic The vector space A is isomorphic to the vector space B if there exists a one-to-one correspondence between their elements which preserves sums and there is a one-to-one correspondence between the scalars which preserves sums and products.

Definition: Subspace Vector space B is a subspace of vector space A if all of the elements of B are contained in A and they share the same scalars.

Definition: Linear Combination Given vectors a_1, \dots, a_n the vector b is a linear combination of the vectors if we can find scalars λ_i such that

$$b = \lambda_1 a_1 + \dots + \lambda_n a_n = \sum_{k=1}^n \lambda_k a_k$$

Definition: Linearly Independent If there exists scalars λ_i such that

$$\lambda_1 a_1 + \dots + \lambda_n a_n = 0$$

and at least one of the λ_i is not zero then the vectors a_1, \dots, a_n are linearly dependent. If no such scalars exist then the vectors are linearly independent.

Definition: Span If every vector can be written as a linear combination of a fixed set of vectors a_1, \dots, a_n then this set of vectors is said to span the vector space.

Definition: Basis If a set of vectors a_1, \dots, a_n is linearly independent and spans a vector space A then the vectors form a basis for A .

Definition: Dimension The dimension of a vector space is the number of basis elements, which is unique since all bases of a vector space have the same number of elements.

Quadratic Forms[?]

For vector space \mathbb{V} over field \mathbb{F} , characteristic $\neq 2$:

Map $f : \mathbb{V} \rightarrow \mathbb{F}$, with

$$f(\lambda x) = \lambda^2 f(x), \forall \lambda \in \mathbb{F}, x \in \mathbb{V}$$

$f(x) = b(x, x)$, where

$$b : \mathbb{V} \times \mathbb{V} \rightarrow \mathbb{F}, \text{ given by}$$

$$b(x, y) := \frac{1}{2}(f(x+y) - f(x) - f(y))$$

is a symmetric bilinear form

Quadratic spaces, Clifford Maps[?, ?]

A quadratic space is the pair (\mathbb{V}, f) , where f is a quadratic form on \mathbb{V}

A Clifford map is a vector space homomorphism

$$\rho : \mathbb{V} \rightarrow \mathbb{A}$$

where \mathbb{A} is an associated algebra, and

$$(\rho v)^2 = f(v), \quad \forall v \in \mathbb{V}$$

Universal Clifford algebras[?]

The *universal Clifford algebra* $Cl(f)$ for the quadratic space (\mathbb{V}, f) is the algebra generated by the image of the Clifford map ρ_f such that $Cl(f)$ is the universal initial object such that \forall suitable algebra \mathbb{A} with Clifford map $\phi_{\mathbb{A}} \exists$ a homomorphism

$$P_{\mathbb{A}} : Cl(f) \rightarrow \mathbb{A}$$

$$\rho_{\mathbb{A}} = P_{\mathbb{A}} \circ \rho_f$$

Real Clifford algebras $\mathbb{R}_{p,q}$ [?]

The real quadratic space $\mathbb{R}^{p,q}$ is \mathbb{R}^{p+q} with

$$\phi(x) := - \sum_{k=-q}^{-1} x_k^2 + \sum_{k=1}^p x_k^2$$

For each $p, q \in \mathbb{N}$, the real universal Clifford algebra for $\mathbb{R}^{p,q}$ is called $\mathbb{R}_{p,q}$

$\mathbb{R}_{p,q}$ is isomorphic to some matrix algebra over one of: $\mathbb{R}, \mathbb{R} \oplus \mathbb{R}, \mathbb{C}, \mathbb{H}, \mathbb{H} \oplus \mathbb{H}$

For example, $\mathbb{R}_{1,1} \cong \mathbb{R}(2)$

Notation for integer sets

For $S \subseteq \mathbb{Z}$, define

$$\sum_{k \in S} f_k := \sum_{k=\min S, k \in S}^{\max S} f_k$$

$$\prod_{k \in S} f_k := \prod_{k=\min S, k \in S}^{\max S} f_k$$

$$\mathbb{P}(S) := \text{the power set of } S$$

For $m \leq n \in \mathbb{Z}$, define

$$\zeta(m, n) := \{m, m+1, \dots, n-1, n\} \setminus \{0\}$$

Frames for Clifford algebras[?, ?, ?]

A *frame* is an ordered basis $(\gamma_{-q}, \dots, \gamma_p)$ for $\mathbb{R}^{p,q}$ which puts a quadratic form into the canonical form ϕ

For $p, q \in \mathbb{N}$, embed the frame for $\mathbb{R}^{p,q}$ into $\mathbb{R}_{p,q}$ via the maps

$$\gamma : \zeta(-q, p) \rightarrow \mathbb{R}^{p,q}$$

$$\rho : \mathbb{R}^{p,q} \rightarrow \mathbb{R}_{p,q}$$

$$(\rho\gamma k)^2 = \phi\gamma k = \text{sgn } k$$

Real frame groups[?, ?]

For $p, q \in \mathbb{N}$, define the real *frame group* $\mathbb{G}_{p,q}$ via the map

$$g : \zeta(-q, p) \rightarrow \mathbb{G}_{p,q}$$

with generators and relations

$$\langle \mu, g_k | \mu g_k = g_k \mu, \quad \mu^2 = 1,$$

$$(g_k)^2 = \begin{cases} \mu, & \text{if } k < 0 \\ 1 & \text{if } k > 0 \end{cases}$$

$$g_k g_m = \mu g_m g_k \quad \forall k \neq m \rangle$$

Canonical products[?, ?, ?]

The real frame group $\mathbb{G}_{p,q}$ has order 2^{p+q+1}

Each member w can be expressed as the canonically ordered product

$$\begin{aligned} w &= \mu^a \prod_{k \in T} g_k \\ &= \mu^a \prod_{k=-q, k \neq 0}^p g_k^{b_k} \end{aligned}$$

where $T \subseteq \zeta(-q, p)$, $a, b_k \in \{0, 1\}$

Clifford algebra of frame group[?, ?, ?, ?]

For $p, q \in \mathbb{N}$ embed $\mathbb{G}_{p,q}$ into $\mathbb{R}_{p,q}$ via the map

$$\begin{aligned} \alpha \mathbb{G}_{p,q} &\rightarrow \mathbb{R}_{p,q} \\ \alpha 1 &:= 1, \quad \alpha \mu := -1 \\ \alpha g_k &:= \rho \gamma_k, \quad \alpha(gh) := (\alpha g)(\alpha h) \end{aligned}$$

Define *basis elements* via the map

$$e : \mathbb{P}\zeta(-q, p) \rightarrow \mathbb{R}_{p,q}, \quad e_T := \alpha \prod_{k \in T} g_k$$

Each $a \in \mathbb{R}_{p,q}$ can be expressed as

$$a = \sum_{T \subseteq \zeta(-q, p)} a_T e_T$$

Neutral matrix representations[?, ?, ?]

The *representation map* P_m and *representation matrix* R_m make the following diagram

$$\begin{array}{ccc} \mathbb{R}_{m,m} & \xrightarrow{\text{coord}} & \mathbb{R}^{4^m} \\ \downarrow P_m & & \downarrow R_m \\ \text{commute:} & & \\ \mathbb{V} & & \mathbb{V} \\ \downarrow & & \downarrow \\ \mathbb{R}(2^m) & \xrightarrow{\text{reshape}} & \mathbb{R}^{4^m} \\ \text{--- CliffordAlgebra.input ---} & & \end{array}$$

=====
CliffordAlgebra examples
=====
```

`CliffordAlgebra(n,K,Q)` defines a vector space of dimension 2^n over the field K with a given quadratic form Q . If $\{e_1..e_n\}$ is a basis for K^n then

```
{ 1,
  e(i)          1 <= i <= n,
  e(i1)*e(i2)   1 <= i1 < i2 <= n,
  ...,
  e(1)*e(2)*...*e(n) }
```

is a basis for the Clifford algebra. The algebra is defined by the relations

```
e(i)*e(i) = Q(e(i))
e(i)*e(j) = -e(j)*e(i), for i != j
```

Examples of Clifford Algebras are gaussians (complex numbers), quaternions, exterior algebras and spin algebras.

```
=====
The Complex Numbers as a Clifford Algebra
=====
```

This is the field over which we will work, rational functions with integer coefficients.

```
K := Fraction Polynomial Integer
Fraction Polynomial Integer
Type: Domain
```

We use this matrix for the quadratic form.

```
m := matrix [ [-1] ]
[- 1]
Type: Matrix Integer
```

We get complex arithmetic by using this domain.

```
C := CliffordAlgebra(1, K, quadraticForm m)
CliffordAlgebra(1,Fraction Polynomial Integer,MATRIX)
Type: Domain
```

Here is i , the usual square root of -1 .

```
i: C := e(1)
e
1
Type: CliffordAlgebra(1,Fraction Polynomial Integer,MATRIX)
```

Here are some examples of the arithmetic.

```

x := a + b * i
a + b e
1
Type: CliffordAlgebra(1,Fraction Polynomial Integer,MATRIX)

```

```

y := c + d * i
c + d e
1
Type: CliffordAlgebra(1,Fraction Polynomial Integer,MATRIX)

```

```

x * y
- b d + a c + (a d + b c)e
1
Type: CliffordAlgebra(1,Fraction Polynomial Integer,MATRIX)

```

```

=====
The Quaternion Numbers as a Clifford Algebra
=====

```

This is the field over which we will work, rational functions with integer coefficients.

```

K := Fraction Polynomial Integer
Fraction Polynomial Integer
Type: Domain

```

We use this matrix for the quadratic form.

```

m := matrix [ [-1,0],[0,-1] ]
+- 1  0 +
|      |
+ 0  - 1+
Type: Matrix Integer

```

The resulting domain is the quaternions.

```

H := CliffordAlgebra(2, K, quadraticForm m)
CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)
Type: Domain

```

We use Hamilton's notation for i, j, k.

```

i: H := e(1)
e
1
Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

j: H := e(2)
e

```

```

2
Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

k: H := i * j
e e
1 2
Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

x := a + b * i + c * j + d * k
a + b e + c e + d e e
1 2 1 2
Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

y := e + f * i + g * j + h * k
e + f e + g e + h e e
1 2 1 2
Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

x + y
e + a + (f + b)e + (g + c)e + (h + d)e e
1 2 1 2
Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

x * y
- d h - c g - b f + a e + (c h - d g + a f + b e)e
1
+
(- b h + a g + d f + c e)e + (a h + b g - c f + d e)e e
2 1 2
Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

y * x
- d h - c g - b f + a e + (- c h + d g + a f + b e)e
1
+
(b h + a g - d f + c e)e + (a h - b g + c f + d e)e e
2 1 2
Type: CliffordAlgebra(2,Fraction Polynomial Integer,MATRIX)

```

```

=====
The Exterior Algebra on a Three Space
=====

```

This is the field over which we will work, rational functions with integer coefficients.

```

K := Fraction Polynomial Integer
Fraction Polynomial Integer
Type: Domain

```

If we chose the three by three zero quadratic form, we obtain the exterior algebra on $e(1), e(2), e(3)$.

```
Ext := CliffordAlgebra(3, K, quadraticForm 0)
      CliffordAlgebra(3, Fraction Polynomial Integer, MATRIX)
      Type: Domain
```

This is a three dimensional vector algebra. We define i, j, k as the unit vectors.

```
i: Ext := e(1)
  e
  1
      Type: CliffordAlgebra(3, Fraction Polynomial Integer, MATRIX)

j: Ext := e(2)
  e
  2
      Type: CliffordAlgebra(3, Fraction Polynomial Integer, MATRIX)

k: Ext := e(3)
  e
  3
      Type: CliffordAlgebra(3, Fraction Polynomial Integer, MATRIX)
```

Now it is possible to do arithmetic.

```
x := x1*i + x2*j + x3*k
    x1 e  + x2 e  + x3 e
      1    2    3
      Type: CliffordAlgebra(3, Fraction Polynomial Integer, MATRIX)

y := y1*i + y2*j + y3*k
    y1 e  + y2 e  + y3 e
      1    2    3
      Type: CliffordAlgebra(3, Fraction Polynomial Integer, MATRIX)

x + y
    (y1 + x1)e  + (y2 + x2)e  + (y3 + x3)e
      1          2          3
      Type: CliffordAlgebra(3, Fraction Polynomial Integer, MATRIX)

x * y + y * x
  0
      Type: CliffordAlgebra(3, Fraction Polynomial Integer, MATRIX)
```

On an n space, a grade p form has a dual $n-p$ form. In particular, in three space the dual of a grade two element identifies

$e1*e2 \rightarrow e3, e2*e3 \rightarrow e1, e3*e1 \rightarrow e2$.

```
dual2 a == coefficient(a,[2,3]) * i + coefficient(a,[3,1]) * j + coefficient(a,[1,2]) * k
Type: Void
```

The vector cross product is then given by this.

```
dual2(x*y)
(x2 y3 - x3 y2)e1 + (- x1 y3 + x3 y1)e2 + (x1 y2 - x2 y1)e3
Type: CliffordAlgebra(3,Fraction Polynomial Integer,MATRIX)
```

```
=====
The Dirac Spin Algebra
=====
```

In this section we will work over the field of rational numbers.

```
K := Fraction Integer
Fraction Integer
Type: Domain
```

We define the quadratic form to be the Minkowski space-time metric.

```
g := matrix [ [1,0,0,0], [0,-1,0,0], [0,0,-1,0], [0,0,0,-1] ]
+1  0  0  0 +
|
|0  -1  0  0 |
|
|0  0  -1  0 |
|
+0  0  0  -1+
Type: Matrix Integer
```

We obtain the Dirac spin algebra used in Relativistic Quantum Field Theory.

```
D := CliffordAlgebra(4,K, quadraticForm g)
CliffordAlgebra(4,Fraction Integer,MATRIX)
Type: Domain
```

The usual notation for the basis is gamma with a superscript. For Axiom input we will use gam(i):

```
gam := [e(i)$D for i in 1..4]
[e1, e2, e3, e4]
Type: List CliffordAlgebra(4,Fraction Integer,MATRIX)
```

There are various contraction identities of the form

```
g(l,t)*gam(l)*gam(m)*gam(n)*gam(r)*gam(s)*gam(t) =
```

$$2*(\text{gam}(s)\text{gam}(m)\text{gam}(n)\text{gam}(r) + \text{gam}(r)\text{gam}(n)\text{gam}(m)\text{gam}(s))$$

where a sum over l and t is implied.

Verify this identity for particular values of m, n, r, s .

```
m := 1; n:= 2; r := 3; s := 4;
```

```
      Type: PositiveInteger
```

```
lhs := reduce(+, [reduce(+, [ g(l,t)*gam(l)*gam(m)*gam(n)*gam(r)*gam(s)*gam(t) for l in 1..4]) for t in 1
- 4e e e e
  1 2 3 4
```

```
      Type: CliffordAlgebra(4,Fraction Integer,MATRIX)
```

```
rhs := 2*(gam s * gam m*gam n*gam r + gam r*gam n*gam m*gam s)
- 4e e e e
  1 2 3 4
```

```
      Type: CliffordAlgebra(4,Fraction Integer,MATRIX)
```

)abbrev domain CLIF CliffordAlgebra
++ Author: Stephen M. Watt
++ Date Created: August 1988
++ Date Last Updated: May 17, 1991
++ Description:
++ CliffordAlgebra(n, K, Q) defines a vector space of dimension \spad{2**n}
++ over K, given a quadratic form Q on \spad{K**n}.
++
++ If \spad{e[i]}, \spad{1<=i<=n} is a basis for \spad{K**n} then
++ 1, \spad{e[i]} (\spad{1<=i<=n}), \spad{e[i1]*e[i2]}
++ (\spad{1<=i1<i2<=n}), ..., \spad{e[1]*e[2]*...*e[n]}
++ is a basis for the Clifford Algebra.
++
++ The algebra is defined by the relations\br
++ \tab{5}\spad{e[i]*e[j] = -e[j]*e[i]} (\spad{i ~~= j}),\br
++ \tab{5}\spad{e[i]*e[i] = Q(e[i])}
++
++ Examples of Clifford Algebras are: gaussians, quaternions, exterior
++ algebras and spin algebras.

CliffordAlgebra(n, K, Q): T == Impl where
  n: PositiveInteger

— Complex.help —

=====
Complex examples

=====

The Complex constructor implements complex objects over a commutative ring R. Typically, the ring R is Integer, Fraction Integer, Float or DoubleFloat. R can also be a symbolic type, like Polynomial Integer.

Complex objects are created by the complex operation.

```
a := complex(4/3,5/2)
      4      5
      - + - %i
      3      2
                                     Type: Complex Fraction Integer
```

```
b := complex(4/3,-5/2)
      4      5
      - - - %i
      3      2
                                     Type: Complex Fraction Integer
```

The standard arithmetic operations are available.

```
a + b
      8
      -
      3
                                     Type: Complex Fraction Integer
```

```
a - b
      5%i
                                     Type: Complex Fraction Integer
```

```
a * b
      289
      ---
      36
                                     Type: Complex Fraction Integer
```

If R is a field, you can also divide the complex objects.

```
a / b
      161      240
      - --- + --- %i
      289      289
                                     Type: Complex Fraction Integer
```

We can view the last object as a fraction of complex integers.

```
% :: Fraction Complex Integer
```

$$\frac{-15 + 8i}{15 + 8i}$$

Type: Fraction Complex Integer

The predefined macro %i is defined to be complex(0,1).

$$\frac{3.4 + 6.7 * \%i}{3.4 + 6.7 \%i}$$

Type: Complex Float

You can also compute the conjugate and norm of a complex number.

$$\frac{\text{conjugate } a}{4 - 5i}$$

Type: Complex Fraction Integer

$$\frac{\text{norm } a}{289}$$

Type: Fraction Integer

The real and imag operations are provided to extract the real and imaginary parts, respectively.

$$\frac{\text{real } a}{4}$$

Type: Fraction Integer

$$\frac{\text{imag } a}{5}$$

Type: Fraction Integer

The domain Complex Integer is also called the Gaussian integers. If R is the integers (or, more generally, a EuclideanDomain), you can compute greatest common divisors.

$$\frac{\text{gcd}(13 - 13i, 31 + 27i)}{5 + i}$$

Type: Complex Integer

You can also compute least common multiples.

```
lcm(13 - 13*i, 31 + 27*i)
143 - 39*i
Type: Complex Integer
```

You can factor Gaussian integers.

```
factor(13 - 13*i)
- (1 + i)(2 + 3*i)(3 + 2*i)
Type: Factored Complex Integer
```

```
factor complex(2,0)
      2
- %i (1 + %i)
Type: Factored Complex Integer
```

— ContinuedFraction.help —

===== ContinuedFraction examples =====

Continued fractions have been a fascinating and useful tool in mathematics for well over three hundred years. Axiom implements continued fractions for fractions of any Euclidean domain. In practice, this usually means rational numbers. In this section we demonstrate some of the operations available for manipulating both finite and infinite continued fractions.

The ContinuedFraction domain is a field and therefore you can add, subtract, multiply and divide the fractions.

The continuedFraction operation converts its fractional argument to a continued fraction.

```
c := continuedFraction(314159/100000)
      1 |   1 |   1 |   1 |   1 |   1 |   1 |
3 + +---+ + +---+ + +---+ + +---+ + +---+ + +---+ + +---+
   | 7   | 15   | 1   | 25   | 1   | 7   | 4
                                Type: ContinuedFraction Integer
```

This display is a compact form of the bulkier

```
3 +
  -----
  7 +
    -----
    15 +
        -----
        1 +
            -----
            25 +
                -----
                1 +
                    -----
                    7 +
                        -----
                        1
                        4
```

You can write any rational number in a similar form. The fraction will be finite and you can always take the "numerators" to be 1. That is, any rational number can be written as a simple, finite continued fraction of the form

```
a(1) +
      1
```

$$\begin{array}{r}
 \text{-----} \\
 a(2) + \frac{1}{\text{-----}} \\
 \quad a(3) + \frac{1}{\text{-----}} \\
 \quad \quad \cdot \\
 \quad \quad \cdot \\
 \quad \quad \cdot \\
 \quad \quad \quad \frac{1}{\text{-----}} \\
 \quad \quad \quad a(n-1) + \frac{1}{\text{-----}} \\
 \quad \quad \quad \quad a(n)
 \end{array}$$

The $a(i)$ are called partial quotients and the operation `partialQuotients` creates a stream of them.

```
partialQuotients c
[3,7,15,1,25,1,7,4]
Type: Stream Integer
```

By considering more and more of the fraction, you get the convergents. For example, the first convergent is $a(1)$, the second is $a(1) + 1/a(2)$ and so on.

```
convergents c
22 333 355 9208 9563 76149 314159
[3,--,---,---,----,----,-----,-----]
7 106 113 2931 3044 24239 100000
Type: Stream Fraction Integer
```

Since this is a finite continued fraction, the last convergent is the original rational number, in reduced form. The result of `approximants` is always an infinite stream, though it may just repeat the "last" value.

```
approximants c
22 333 355 9208 9563 76149 314159
[3,--,---,---,----,----,-----,-----]
7 106 113 2931 3044 24239 100000
Type: Stream Fraction Integer
```

Inverting `c` only changes the partial quotients of its fraction by inserting a 0 at the beginning of the list.

```
pq := partialQuotients(1/c)
[0,3,7,15,1,25,1,7,4]
Type: Stream Integer
```

Do this to recover the original continued fraction from this list of

partial quotients. The three-argument form of the `continuedFraction` operation takes an element which is the whole part of the fraction, a stream of elements which are the numerators of the fraction, and a stream of elements which are the denominators of the fraction.

```
continuedFraction(first pq, repeating [1], rest pq)
  1 |    1 |    1 |    1 |    1 |    1 |    1 |    1 |
+---+ + +---+ + +---+ + +---+ + +---+ + +---+ + +---+ + +---+
| 3      | 7      | 15      | 1      | 25      | 1      | 7      | 4
Type: ContinuedFraction Integer
```

The streams need not be finite for `continuedFraction`. Can you guess which irrational number has the following continued fraction? See the end of this section for the answer.

```
z:=continuedFraction(3, repeating [1], repeating [3,6])
  1 |    1 |    1 |    1 |    1 |    1 |    1 |    1 |    1 |
3 + +---+ + +---+ + +---+ + +---+ + +---+ + +---+ + +---+ + +---+
  | 3      | 6      | 3      | 6      | 3      | 6      | 3      | 6      | 3
+
  1 |
+---+ + ...
  | 6
Type: ContinuedFraction Integer
```

In 1737 Euler discovered the infinite continued fraction expansion

$$e - 1 = \cfrac{1}{2 + \cfrac{1}{1 + \cfrac{1}{6 + \cfrac{1}{10 + \cfrac{1}{14 + \dots}}}}}$$

We use this expansion to compute rational and floating point approximations of e . For this and other interesting expansions, see C. D. Olds, *Continued Fractions*, New Mathematical Library, (New York: Random House, 1963), pp. 134--139.}

By looking at the above expansion, we see that the whole part is 0 and the numerators are all equal to 1. This constructs the stream of denominators.

```
dens:Stream Integer := cons(1, generate((x+>x+4),6))
[1,6,10,14,18,22,26,30,34,38,...]
Type: Stream Integer
```

$$\begin{array}{c}
 \text{-----} \\
 2 + \quad 25 \\
 \text{-----} \\
 2 + \quad 49 \\
 \text{-----} \\
 2 + \quad 81 \\
 \text{-----} \\
 2 + \dots
 \end{array}$$

Let's use this expansion to compute rational and floating point approximations for pi.

```

cf := continuedFraction(1,[(2*i+1)**2 for i in 0..],repeating [2])
      1 |   9 |   25 |   49 |   81 |  121 |  169 |  225 |
1 + +---+ + +---+ + +---+ + +---+ + +---+ + +---+ + +---+
   | 2   | 2   | 2   | 2   | 2   | 2   | 2   | 2   |
+
  289 |   361 |
+-----+ + +-----+ + ...
   | 2   | 2
Type: ContinuedFraction Integer

```

```

ccf := convergents cf
      3 15 105 315 3465 45045 45045 765765 14549535
[1,-,--,---,---,---,---,---,---,---,---,---,---,...]
      2 13 76 263 2578 36979 33976 622637 11064338
Type: Stream Fraction Integer

piConvergents := [4/p for p in ccf]
      8 52 304 1052 10312 147916 135904 2490548 44257352
[4,-,--,---,---,---,---,---,---,---,---,---,---,...]
      3 15 105 315 3465 45045 45045 765765 14549535
Type: Stream Fraction Integer

```

As you can see, the values are converging to
 $\pi = 3.14159265358979323846\dots$, but not very quickly.

```

piConvergents :: Stream Float
[4.0, 2.6666666666 666666667, 3.4666666666 666666667,
 2.8952380952 380952381, 3.3396825396 825396825, 2.9760461760 461760462,
 3.2837384837 384837385, 3.0170718170 718170718, 3.2523659347 188758953,
 3.0418396189 294022111, ...]
Type: Stream Float

```

You need not restrict yourself to continued fractions of integers.
 Here is an expansion for a quotient of Gaussian integers.

```

continuedFraction((- 122 + 597*i)/(4 - 4*i))
      1 |   1 |
- 90 + 59*i + +-----+ + +-----+

```

```

      | 1 - 2%i      | - 1 + 2%i
      Type: ContinuedFraction Complex Integer

```

This is an expansion for a quotient of polynomials in one variable with rational number coefficients.

```

r : Fraction UnivariatePolynomial(x,Fraction Integer)
  Type: Void

r := ((x - 1) * (x - 2)) / ((x-3) * (x-4))
      2
      x  - 3x + 2
      -----
      2
      x  - 7x + 12
      Type: Fraction UnivariatePolynomial(x,Fraction Integer)

continuedFraction r
      1      |      1      |
1 + +-----+ + +-----+
   | 1      9      | 16      40
   | - x - -      | -- x - --
   | 4      8      | 3      3
      Type: ContinuedFraction UnivariatePolynomial(x,Fraction Integer)

```

To conclude this section, we give you evidence that

```

z = 3 +
      1
      -----
      3 +
            1
            -----
            6 +
                  1
                  -----
                  3 +
                        1
                        -----
                        6 +
                              1
                              -----
                              3 + ...

```

is the expansion of `sqrt(11)`.

```

[i*i for i in convergents(z) :: Stream Float]

```

)abbrev domain CONTFRAC ContinuedFraction
++ Author: Stephen M. Watt
++ Date Created: January 1987
  
```

```

++ Change History: 7 October 1991
++ Description:
++ \spadtype{ContinuedFraction} implements general
++ continued fractions. This version is not restricted to simple,
++ finite fractions and uses the \spadtype{Stream} as a
++ representation. The arithmetic functions assume that the
++ approximants alternate below/above the convergence point.
++ This is enforced by ensuring the partial numerators and partial
++ denominators are greater than 0 in the Euclidean domain view of \spad{R}
++ (i.e. \spad{sizeLess?(0, x)}).

```

```
ContinuedFraction(R): Exports == Implementation where

++ wholePart(x) extracts the whole part of \spadvar{x}. That
++ is, if \spad{x = continuedFraction(b0, [a1,a2,a3,...],
++ [b1,b2,b3,...])}, then \spad{wholePart(x) = b0}.

reducedForm:        % -> %
++ reducedForm(x) puts the continued fraction \spadvar{x} in
++ reduced form, i.e. the function returns an equivalent
++ continued fraction of the form
++ \spad{continuedFraction(b0,[1,1,1,...],[b1,b2,b3,...])}.

approximants:       % -> Stream Q
++ approximants(x) returns the stream of approximants of the
++ continued fraction \spadvar{x}. If the continued fraction is
++ finite, then the stream will be infinite and periodic with
++ period 1.

convergents:        % -> Stream Q
++ convergents(x) returns the stream of the convergents of the
++ continued fraction \spadvar{x}. If the continued fraction is
++ finite, then the stream will be finite.

numerators:         % -> Stream R
++ numerators(x) returns the stream of numerators of the
++ approximants of the continued fraction \spadvar{x}. If the
++ continued fraction is finite, then the stream will be finite.

denominators:       % -> Stream R
++ denominators(x) returns the stream of denominators of the
++ approximants of the continued fraction \spadvar{x}. If the
++ continued fraction is finite, then the stream will be finite.

extend:             (%,Integer) -> %
++ extend(x,n) causes the first \spadvar{n} entries in the
++ continued fraction \spadvar{x} to be computed. Normally
++ entries are only computed as needed.

complete:           % -> %
++ complete(x) causes all entries in \spadvar{x} to be computed.
++ Normally entries are only computed as needed. If \spadvar{x}
++ is an infinite continued fraction, a user-initiated interrupt is
++ necessary to stop the computation.

DecimalExpansion examples

=====

All rationals have repeating decimal expansions. Operations to access the individual digits of a decimal expansion can be obtained by converting the value to RadixExpansion(10).

The operation decimal is used to create this expansion of type DecimalExpansion.

```

r := decimal(22/7)
-----
3.142857
Type: DecimalExpansion

```

Arithmetic is exact.

```

r + decimal(6/7)
4
Type: DecimalExpansion

```

The period of the expansion can be short or long ...

```

[decimal(1/i) for i in 350..354]
-----
[0.00285714, 0.002849, 0.0028409, 0.00283286118980169971671388101983,

Denavit-Hartenberg Matrices

Homogeneous Transformations

The study of robot manipulation is concerned with the relationship between objects, and between objects and manipulators. In this chapter we will develop the representation necessary to describe these relationships. Similar problems of representation have already been solved in the field of computer graphics, where the relationship between objects must also be

described. Homogeneous transformations are used in this field and in computer vision [Duda] [Roberts63] [Roberts65]. These transformations were employed by Denavit to describe linkages [Denavit] and are now used to describe manipulators [Pieper] [Paul72] [Paul77b].

We will first establish notation for vectors and planes and then introduce transformations on them. These transformations consist primarily of translation and rotation. We will then show that these transformations can also be considered as coordinate frames in which to represent objects, including the manipulator. The inverse transformation will then be introduced. A later section describes the general rotation transformation representing a rotation about a vector. An algorithm is then described to find the equivalent axis and angle of rotations represented by any given transformation. A brief section on stretching and scaling transforms is included together with a section on the perspective transformation. The chapter concludes with a section on transformation equations.

Notation

In describing the relationship between objects we will make use of point vectors, planes, and coordinate frames. Point vectors are denoted by lower case, bold face characters. Planes are denoted by script characters, and coordinate frames by upper case, bold face characters. For example:

vectors	$\mathbf{v}, \mathbf{x1}, \mathbf{x}$
planes	\mathcal{P}, \mathcal{Q}
coordinate frames	$\mathbf{I}, \mathbf{A}, \mathbf{CONV}$

We will use point vectors, planes, and coordinate frames as variables which have associated values. For example, a point vector has as value its three Cartesian coordinate components.

If we wish to describe a point in space, which we will call p , with respect to a coordinate frame \mathbf{E} , we will use a vector which we will call \mathbf{v} . We will write this as

$${}^E\mathbf{v}$$

The leading superscript describes the defining coordinate frame.

We might also wish to describe this same point, p , with respect to a different coordinate frame, for example \mathbf{H} , using a vector \mathbf{w} as

$${}^H\mathbf{w}$$

\mathbf{v} and \mathbf{w} are two vectors which probably have different component values and $\mathbf{v} \neq \mathbf{w}$ even though both vectors describe the same point p . The case might also exist of a vector \mathbf{a} describing a point 3 inches above any frame

$${}^{F^1}\mathbf{a} \quad {}^{F^2}\mathbf{a}$$

In this case the vectors are identical but describe different points. Frequently, the defining frame will be obvious from the text and the superscripts will be left off. In many cases the

name of the vector will be the same as the name of the object described, for example, the tip of a pin might be described by a vector **tip** with respect to a frame **BASE** as

$${}^{BASE}\mathbf{tip}$$

If it were obvious from the text that we were describing the vector with respect to **BASE** then we might simply write

$$\mathbf{tip}$$

If we also wish to describe this point with respect to another coordinate frame say, **HAND**, then we must use another vector to describe this relationship, for example

$${}^{HAND}\mathbf{tv}$$

${}^{HAND}\mathbf{tv}$ and **tip** both describe the same feature but have different values. In order to refer to individual components of coordinate frames, point vectors, or planes, we add subscripts to indicate the particular component. For example, the vector ${}^{HAND}\mathbf{tv}$ has components ${}^{HAND}\mathbf{tv}_x$, ${}^{HAND}\mathbf{tv}_y$, ${}^{HAND}\mathbf{tv}_z$.

Vectors

The homogeneous coordinate representation of objects in n -space is an $(n + 1)$ -space entity such that a particular perspective projection recreates the n -space. This can also be viewed as the addition of an extra coordinate to each vector, a scale factor, such that the vector has the same meaning if each component, including the scale factor, is multiplied by a constant.

A point vector

$$\mathbf{v} = a\mathbf{i} + b\mathbf{j} + c\mathbf{k} \quad (1.1)$$

where **i**, **j**, and **k** are unit vectors along the x , y , and z coordinate axes, respectively, is represented in homogeneous coordinates as a column matrix

$$\mathbf{v} = \begin{bmatrix} \mathbf{x} \\ \mathbf{y} \\ \mathbf{z} \\ \mathbf{w} \end{bmatrix} \quad (1.2)$$

where

$$\begin{aligned} \mathbf{a} &= \mathbf{x}/\mathbf{w} \\ \mathbf{b} &= \mathbf{y}/\mathbf{w} \\ \mathbf{c} &= \mathbf{z}/\mathbf{w} \end{aligned} \quad (1.3)$$

Thus the vector $3\mathbf{i} + 4\mathbf{j} + 5\mathbf{k}$ can be represented as $[3, 4, 5, 1]^T$ or as $[6, 8, 10, 2]^T$ or again as $[-30, -40, -50, -10]^T$, etc. The superscript T indicates the transpose of the row vector into a column vector. The vector at the origin, the null vector, is represented as $[0, 0, 0, n]^T$ where n is any non-zero scale factor. The vector $[0, 0, 0, 0]^T$ is undefined. Vectors of the form $[a, b, c, 0]^T$ represent vectors at infinity and are used to represent directions; the addition of any other finite vector does not change their value in any way.

We will also make use of the vector dot and cross products. Given two vectors

$$\begin{aligned}\mathbf{a} &= a_x\mathbf{i} + a_y\mathbf{j} + a_z\mathbf{k} \\ \mathbf{b} &= b_x\mathbf{i} + b_y\mathbf{j} + b_z\mathbf{k}\end{aligned}\tag{1.4}$$

we define the vector dot product, indicated by “.” as

$$\mathbf{a} \cdot \mathbf{b} = a_x b_x + a_y b_y + a_z b_z\tag{1.5}$$

The dot product of two vectors is a scalar. The cross product, indicated by an “ \times ”, is another vector perpendicular to the plane formed by the vectors of the product and is defined by

$$\mathbf{a} \times \mathbf{b} = (a_y b_z - a_z b_y)\mathbf{i} + (a_z b_x - a_x b_z)\mathbf{j} + (a_x b_y - a_y b_x)\mathbf{k}\tag{1.6}$$

This definition is easily remembered as the expansion of the determinant

$$\mathbf{a} \times \mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_x & a_y & a_z \\ b_x & b_y & b_z \end{vmatrix}\tag{1.7}$$

Planes

A plane is represented as a row matrix

$$\mathcal{P} = [a, b, c, d]\tag{1.8}$$

such that if a point \mathbf{v} lies in a plane \mathcal{P} the matrix product

$$\mathcal{P} \mathbf{v} = 0\tag{1.9}$$

or in expanded form

$$xa + yb + zc + wd = 0\tag{1.10}$$

If we define a constant

$$m = +\sqrt{a^2 + b^2 + c^2}\tag{1.11}$$

and divide Equation 1.10 by wm we obtain

$$\frac{x}{w} \frac{a}{m} + \frac{y}{w} \frac{b}{m} + \frac{z}{w} \frac{c}{m} = -\frac{d}{m} \quad (1.12)$$

The left hand side of Equation 1.12 is the vector dot product of two vectors $(x/w)\mathbf{i} + (y/w)\mathbf{j} + (z/w)\mathbf{k}$ and $(a/m)\mathbf{i} + (b/m)\mathbf{j} + (c/m)\mathbf{k}$ and represents the directed distance of the point $(x/w)\mathbf{i} + (y/w)\mathbf{j} + (z/w)\mathbf{k}$ along the vector $(a/m)\mathbf{i} + (b/m)\mathbf{j} + (c/m)\mathbf{k}$. The vector $(a/m)\mathbf{i} + (b/m)\mathbf{j} + (c/m)\mathbf{k}$ can be interpreted as the outward pointing normal of a plane situated a distance $-d/m$ from the origin in the direction of the normal. Thus a plane \mathcal{P} parallel to the x,y plane, one unit along the z axis, is represented as

$$\mathcal{P} = [0, 0, 1, -1] \quad (1.13)$$

$$\text{or as } \mathcal{P} = [0, 0, 2, -2] \quad (1.14)$$

$$\text{or as } \mathcal{P} = [0, 0, -100, 100] \quad (1.15)$$

A point $\mathbf{v} = [10, 20, 1, 1]$ should lie in this plane

$$[0, 0, -100, 100] \begin{bmatrix} 10 \\ 20 \\ 1 \\ 1 \end{bmatrix} = 0 \quad (1.16)$$

or

$$[0, 0, 1, -1] \begin{bmatrix} -5 \\ -10 \\ -.5 \\ -.5 \end{bmatrix} = 0 \quad (1.17)$$

The point $\mathbf{v} = [0, 0, 2, 1]$ lies above the plane

$$[0, 0, 2, -2] \begin{bmatrix} 0 \\ 0 \\ 2 \\ 1 \end{bmatrix} = 2 \quad (1.18)$$

and $\mathcal{P} \mathbf{v}$ is indeed positive, indicating that the point is outside the plane in the direction of the outward pointing normal. A point $\mathbf{v} = [0, 0, 0, 1]$ lies below the plane

$$[0, 0, 1, -1] \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} = -1 \quad (1.19)$$

The plane $[0, 0, 0, 0]$ is undefined.

Transformations

A transformation of the space \mathbf{H} is a 4x4 matrix and can represent translation, rotation, stretching, and perspective transformations. Given a point \mathbf{u} , its transformation \mathbf{v} is represented by the matrix product

$$\mathbf{v} = \mathbf{H}\mathbf{u} \quad (1.20)$$

The corresponding plane transformation \mathcal{P} to \mathcal{Q} is

$$\mathcal{Q} = \mathcal{P} \mathbf{H}^{-1} \quad (1.21)$$

as we require that the condition

$$\mathcal{Q} \mathbf{v} = \mathcal{P} \mathbf{u} \quad (1.22)$$

is invariant under all transformations. To verify this we substitute from Equations 1.20 and 1.21 into the left hand side of 1.22 and we obtain on the right hand side $\mathbf{H}^{-1}\mathbf{H}$ which is the identity matrix \mathbf{I}

$$\mathcal{P} \mathbf{H}^{-1} \mathbf{H} \mathbf{u} = \mathcal{P} \mathbf{u} \quad (1.23)$$

Translation Transformation

The transformation \mathbf{H} corresponding to a translation by a vector $a\mathbf{i} + b\mathbf{j} + c\mathbf{k}$ is

$$\mathbf{H} = \mathbf{Trans}(\mathbf{a}, \mathbf{b}, \mathbf{c}) = \begin{bmatrix} 1 & 0 & 0 & a \\ 0 & 1 & 0 & b \\ 0 & 0 & 1 & c \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.24)$$

Given a vector $\mathbf{u} = [x, y, z, w]^T$ the transformed vector \mathbf{v} is given by

$$\mathbf{H} = \mathbf{Trans}(\mathbf{a}, \mathbf{b}, \mathbf{c}) = \begin{bmatrix} 1 & 0 & 0 & a \\ 0 & 1 & 0 & b \\ 0 & 0 & 1 & c \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ w \end{bmatrix} \quad (1.25)$$

$$\mathbf{v} = \begin{bmatrix} x + aw \\ y + bw \\ z + cw \\ w \end{bmatrix} = \begin{bmatrix} x/w + a \\ y/w + b \\ z/w + c \\ 1 \end{bmatrix} \quad (1.26)$$

The translation may also be interpreted as the addition of the two vectors $(x/w)\mathbf{i} + (y/w)\mathbf{j} + (z/w)\mathbf{k}$ and $a\mathbf{i} + b\mathbf{j} + c\mathbf{k}$.

Every element of a transformation matrix may be multiplied by a non-zero constant without changing the transformation, in the same manner as points and planes. Consider the vector $2\mathbf{i} + 3\mathbf{j} + 2\mathbf{k}$ translated by, or added to $4\mathbf{i} - 3\mathbf{j} + 7\mathbf{k}$

$$\begin{bmatrix} 6 \\ 0 \\ 9 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 4 \\ 0 & 1 & 0 & -3 \\ 0 & 0 & 1 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 2 \\ 3 \\ 2 \\ 1 \end{bmatrix} \quad (1.27)$$

If we multiply the transformation matrix elements by, say, -5, and the vector elements by 2, we obtain

$$\begin{bmatrix} -60 \\ 0 \\ -90 \\ -10 \end{bmatrix} = \begin{bmatrix} -5 & 0 & 0 & -20 \\ 0 & -5 & 0 & 15 \\ 0 & 0 & -5 & -35 \\ 0 & 0 & 0 & -5 \end{bmatrix} \begin{bmatrix} 4 \\ 6 \\ 4 \\ 2 \end{bmatrix} \quad (1.28)$$

which corresponds to the vector $[6, 0, 9, 1]^T$ as before. The point $[2, 3, 2, 1]$ lies in the plane $[1, 0, 0, -2]$

$$[1, 0, 0, -2] \begin{bmatrix} 2 \\ 3 \\ 2 \\ 1 \end{bmatrix} = 0 \quad (1.29)$$

The transformed point is, as we have already found, $[6, 0, 9, 1]^T$. We will now compute the transformed plane. The inverse of the transform is

$$\begin{bmatrix} 1 & 0 & 0 & -4 \\ 0 & 1 & 0 & 3 \\ 0 & 0 & 1 & -7 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

and the transformed plane

$$[1 \ 0 \ 0 \ -6] = [1 \ 0 \ 0 \ -2] \begin{bmatrix} 1 & 0 & 0 & -4 \\ 0 & 1 & 0 & 3 \\ 0 & 0 & 1 & -7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.30)$$

Once again the transformed point lies in the transformed plane

$$[1 \ 0 \ 0 \ -6] \begin{bmatrix} 6 \\ 0 \\ 9 \\ 1 \end{bmatrix} = 0 \quad (1.31)$$

The general translation operation can be represented in Axiom as

— **translate** —

```
translate(x,y,z) ==
matrix(
  [[1,0,0,x],_
   [0,1,0,y],_
   [0,0,1,z],_
   [0,0,0,1]])
```

Rotation Transformations

The transformations corresponding to rotations about the x , y , and z axes by an angle θ are

$$\mathbf{Rot}(\mathbf{x}, \theta) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos \theta & -\sin \theta & 0 \\ 0 & \sin \theta & \cos \theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.32)$$

Rotations can be described in Axiom as functions that return matrices. We can define a function for each of the rotation matrices that correspond to the rotations about each axis. Note that the sine and cosine functions in Axiom expect their argument to be in radians rather than degrees. This conversion is

$$radians = \frac{degrees * \pi}{180}$$

The Axiom code for **Rot(x, degree)** is

— **rotatex** —

```
rotatex(degree) ==
angle := degree * pi() / 180::R
cosAngle := cos(angle)
sinAngle := sin(angle)
matrix(
  [[1, 0, 0, 0], _
   [0, cosAngle, -sinAngle, 0], _
   [0, sinAngle, cosAngle, 0], _
   [0, 0, 0, 1]])
```

$$\mathbf{Rot}(\mathbf{y}, \theta) = \begin{bmatrix} \cos \theta & 0 & \sin \theta & 0 \\ 0 & 1 & 0 & 0 \\ -\sin \theta & 0 & \cos \theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.33)$$

The Axiom code for $\mathbf{Rot}(\mathbf{y}, \text{degree})$ is

```

— rotatey —

rotatey(degree) ==
angle := degree * pi() / 180::R
cosAngle := cos(angle)
sinAngle := sin(angle)
matrix(_
[[ cosAngle, 0, sinAngle, 0], _
[ 0, 1, 0, 0], _
[-sinAngle, 0, cosAngle, 0], _
[ 0, 0, 0, 1]])

```

$$\mathbf{Rot}(\mathbf{z}, \theta) = \begin{bmatrix} \cos \theta & -\sin \theta & 0 & 0 \\ \sin \theta & \cos \theta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.34)$$

And the Axiom code for $\mathbf{Rot}(\mathbf{z}, \text{degree})$ is

```

— rotatez —

rotatez(degree) ==
angle := degree * pi() / 180::R
cosAngle := cos(angle)
sinAngle := sin(angle)
matrix(_
[[cosAngle, -sinAngle, 0, 0], _
[sinAngle, cosAngle, 0, 0], _
[ 0, 0, 1, 0], _
[ 0, 0, 0, 1]])

```

Let us interpret these rotations by means of an example. Given a point $\mathbf{u} = 7\mathbf{i} + 3\mathbf{j} + 2\mathbf{k}$ what is the effect of rotating it 90° about the \mathbf{z} axis to \mathbf{v} ? The transform is obtained from Equation 1.34 with $\sin \theta = 1$ and $\cos \theta = 0$.

$$\begin{bmatrix} -3 \\ 7 \\ 2 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 7 \\ 3 \\ 2 \\ 1 \end{bmatrix} \quad (1.35)$$

Let us now rotate \mathbf{v} 90° about the y axis to \mathbf{w} . The transform is obtained from Equation 1.33 and we have

$$\begin{bmatrix} 2 \\ 7 \\ 3 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} -3 \\ 7 \\ 2 \\ 1 \end{bmatrix} \quad (1.36)$$

If we combine these two rotations we have

$$\mathbf{v} = \mathbf{Rot}(\mathbf{z}, 90)\mathbf{u} \quad (1.37)$$

$$\text{and } \mathbf{w} = \mathbf{Rot}(\mathbf{y}, 90)\mathbf{v} \quad (1.38)$$

Substituting for \mathbf{v} from Equation 1.37 into Equation 1.38 we obtain

$$\mathbf{w} = \mathbf{Rot}(\mathbf{y}, 90) \mathbf{Rot}(\mathbf{z}, 90) \mathbf{u} \quad (1.39)$$

$$\mathbf{Rot}(\mathbf{y}, 90) \mathbf{Rot}(\mathbf{z}, 90) = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.40)$$

$$\mathbf{Rot}(\mathbf{y}, 90) \mathbf{Rot}(\mathbf{z}, 90) = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.41)$$

thus

$$\mathbf{w} = \begin{bmatrix} 2 \\ 7 \\ 3 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 7 \\ 3 \\ 2 \\ 1 \end{bmatrix} \quad (1.42)$$

as we obtained before.

If we reverse the order of rotations and first rotate 90° about the y axis and then 90° about the z axis, we obtain a different position

$$\mathbf{Rot}(\mathbf{z}, 90)\mathbf{Rot}(\mathbf{y}, 90) = \begin{bmatrix} 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.43)$$

and the point \mathbf{u} transforms into \mathbf{w} as

$$\begin{bmatrix} -3 \\ 2 \\ -7 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 7 \\ 3 \\ 2 \\ 1 \end{bmatrix} \quad (1.44)$$

We should expect this, as matrix multiplication is noncommutative.

$$\mathbf{AB} \neq \mathbf{BA} \quad (1.45)$$

We will now combine the original rotation with a translation $4\mathbf{i} - 3\mathbf{j} + 7\mathbf{k}$. We obtain the translation from Equation 1.27 and the rotation from Equation 1.41. The matrix expression is

$$\mathbf{Trans}(4, -3, 7)\mathbf{Rot}(\mathbf{y}, 90)\mathbf{Rot}(\mathbf{z}, 90) = \begin{bmatrix} 1 & 0 & 0 & 4 \\ 0 & 1 & 0 & -3 \\ 0 & 0 & 1 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & -3 \\ 0 & 1 & 0 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.46)$$

and our point $\mathbf{w} = 7\mathbf{i} + 3\mathbf{j} + 2\mathbf{k}$ transforms into \mathbf{x} as

$$\begin{bmatrix} 6 \\ 4 \\ 10 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & -3 \\ 0 & 1 & 0 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 7 \\ 3 \\ 2 \\ 1 \end{bmatrix} \quad (1.47)$$

Coordinate Frames

We can interpret the elements of the homogeneous transformation as four vectors describing a second coordinate frame. The vector $[0, 0, 0, 1]^T$ lies at the origin of the second coordinate frame. Its transformation corresponds to the right hand column of the transformation matrix. Consider the transform in Equation 1.47

$$\begin{bmatrix} 4 \\ -3 \\ 7 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & -3 \\ 0 & 1 & 0 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} \quad (1.48)$$

The transform of the null vector is $[4, -3, 7, 1]^T$, the right hand column. If we transform vectors corresponding to unit vectors along the x , y , and z axes, we obtain $[4, -2, 7, 1]^T$, $[4, -3, 8, 1]^T$, and $[5, -3, 7, 1]^T$, respectively. Those four vectors form a coordinate frame.

The direction of these unit vectors is formed by subtracting the vector representing the origin of this coordinate frame and extending the vectors to infinity by reducing their scale factors to zero. The direction of the x , y , and z axes of this frame are $[0, 1, 0, 0]^T$, $[0, 0, 1, 0]^T$, and $[1, 0, 0, 0]^T$, respectively. These direction vectors correspond to the first three columns of the transformation matrix. The transformation matrix thus describes the three axis directions and the position of the origin of a coordinate frame rotated and translated away from the reference coordinate frame. When a vector is transformed, as in Equation 1.47, the original vector can be considered as a vector described in the coordinate frame. The transformed vector is the same vector described with respect to the reference coordinate frame.

Relative Transformations

The rotations and translations we have been describing have all been made with respect to the fixed reference coordinate frame. Thus, in the example given,

$$\mathbf{Trans}(4, -3, 7)\mathbf{Rot}(y, 90)\mathbf{Rot}(z, 90) = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & -3 \\ 0 & 1 & 0 & 7 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.49)$$

the frame is first rotated around the reference z axis by 90° , then rotated 90° around the reference y axis, and finally translated by $4\mathbf{i} - 3\mathbf{j} + 7\mathbf{k}$. We may also interpret the operation in the reverse order, from left to right, as follows: the object is first translated by $4\mathbf{i} - 3\mathbf{j} + 7\mathbf{k}$; it is then rotated 90° around the current frames axes, which in this case are the same as the reference axes; it is then rotated 90° about the newly rotated (current) frames axes.

In general, if we postmultiply a transform representing a frame by a second transformation describing a rotation and/or translation, we make that translation and/or rotation with respect to the frame axes described by the first transformation. If we premultiply the frame transformation by a transformation representing a translation and/or rotation, then that translation and/or rotation is made with respect to the base reference coordinate frame. Thus, given a frame \mathbf{C} and a transformation \mathbf{T} , corresponding to a rotation of 90° about the z axis, and a translation of 10 units in the x direction, we obtain a new position \mathbf{X} when the change is made in the base coordinates $\mathbf{X} = \mathbf{TC}$

$$\begin{bmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 20 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & -1 & 0 & 10 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 20 \\ 0 & 0 & -1 & 10 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.50)$$

and a new position \mathbf{Y} when the change is made relative to the frame axes as $\mathbf{Y} = \mathbf{CT}$

$$\begin{bmatrix} 0 & -1 & 0 & 30 \\ 0 & 0 & -1 & 10 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 20 \\ 0 & 0 & -1 & 10 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & -1 & 0 & 10 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.51)$$

Objects

Transformations are used to describe the position and orientation of objects. An object is described by six points with respect to a coordinate frame fixed in the object.

If we rotate the object 90° about the z axis and then 90° about the y axis, followed by a translation of four units in the x direction, we can describe the transformation as

$$\mathbf{Trans}(4, 0, 0)\mathbf{Rot}(y, 90)\mathbf{Rot}(z, 90) = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.52)$$

The transformation matrix represents the operation of rotation and translation on a coordinate frame originally aligned with the reference coordinate frame. We may transform the six points of the object as

$$\begin{bmatrix} 4 & 4 & 6 & 6 & 4 & 4 \\ 1 & -1 & -1 & 1 & 1 & -1 \\ 0 & 0 & 0 & 0 & 4 & 4 \\ 1 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 & -1 & 1 & 1 & -1 \\ 0 & 0 & 0 & 0 & 4 & 4 \\ 0 & 0 & 2 & 2 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} \quad (1.53)$$

It can be seen that the object described bears the same fixed relationship to its coordinate frame, whose position and orientation are described by the transformation. Given an object described by a reference coordinate frame, and a transformation representing the position and orientation of the object's axes, the object can be simply reconstructed, without the necessity of transforming all the points, by noting the direction and orientation of key features with respect to the describing frame's coordinate axes. By drawing the transformed coordinate frame, the object can be related to the new axis directions.

Inverse Transformations

We are now in a position to develop the inverse transformation as the transform which carries the transformed coordinate frame back to the original frame. This is simply the description of the reference coordinate frame with respect to the transformed frame. Suppose the direction of the reference frame x axis is $[0, 0, 1, 0]^T$ with respect to the transformed frame. The y and z axes are $[1, 0, 0, 0]^T$ and $[0, 1, 0, 0]^T$, respectively. The location of the origin is $[0, 0, -4, 1]^T$ with respect to the transformed frame and thus the inverse transformation is

$$\mathbf{T}^{-1} = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & -4 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.54)$$

That this is indeed the transform inverse is easily verified by multiplying it by the transform \mathbf{T} to obtain the identity transform

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & -4 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & 0 & 1 & 4 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.55)$$

In general, given a transform with elements

$$\mathbf{T} = \begin{bmatrix} n_x & o_x & a_x & p_x \\ n_y & o_y & a_y & p_y \\ n_z & o_z & a_z & p_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.56)$$

then the inverse is

$$\mathbf{T}^{-1} = \begin{bmatrix} n_x & n_y & n_z & -\mathbf{p} \cdot \mathbf{n} \\ o_x & o_y & o_z & -\mathbf{p} \cdot \mathbf{o} \\ a_x & a_y & a_z & -\mathbf{p} \cdot \mathbf{a} \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.57)$$

where \mathbf{p} , \mathbf{n} , \mathbf{o} , and \mathbf{a} are the four column vectors and “ \cdot ” represents the vector dot product. This result is easily verified by postmultiplying Equation 1.56 by Equation 1.57.

General Rotation Transformation

We state the rotation transformations for rotations about the x , y , and z axes (Equations 1.32, 1.33 and 1.34). These transformations have a simple geometric interpretation. For example, in the case of a rotation about the z axis, the column representing the z axis will remain constant, while the column elements representing the x and y axes will vary.

We will now develop the transformation matrix representing a rotation around an arbitrary vector \mathbf{k} located at the origin. In order to do this we will imagine that \mathbf{k} is the z axis unit vector of a coordinate frame \mathbf{C}

$$\mathbf{C} = \begin{bmatrix} n_x & o_x & a_x & p_x \\ n_y & o_y & a_y & p_y \\ n_z & o_z & a_z & p_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.58)$$

$$\mathbf{k} = a_x \mathbf{i} + a_y \mathbf{j} + a_z \mathbf{k} \quad (1.59)$$

Rotating around the vector \mathbf{k} is then equivalent to rotating around the z axis of the frame \mathbf{C} .

$$\mathbf{Rot}(\mathbf{k}, \theta) = \mathbf{Rot}({}^{\mathbf{C}}\mathbf{z}, \theta) \quad (1.60)$$

If we are given a frame \mathbf{T} described with respect to the reference coordinate frame, we can find a frame \mathbf{X} which describes the same frame with respect to frame \mathbf{C} as

$$\mathbf{T} = \mathbf{C}\mathbf{X} \quad (1.61)$$

where \mathbf{X} describes the position of \mathbf{T} with respect to frame \mathbf{C} . Solving for \mathbf{X} we obtain

$$\mathbf{X} = \mathbf{C}^{-1}\mathbf{T} \quad (1.62)$$

Rotation \mathbf{T} around \mathbf{k} is equivalent to rotating \mathbf{X} around the z axis of frame \mathbf{C}

$$\mathbf{Rot}(\mathbf{k}, \theta)\mathbf{T} = \mathbf{C}\mathbf{Rot}(\mathbf{z}, \theta)\mathbf{X} \quad (1.63)$$

$$\mathbf{Rot}(\mathbf{k}, \theta)\mathbf{T} = \mathbf{C}\mathbf{Rot}(\mathbf{z}, \theta)\mathbf{C}^{-1}\mathbf{T}. \quad (1.64)$$

Thus

$$\mathbf{Rot}(\mathbf{k}, \theta) = \mathbf{C}\mathbf{Rot}(\mathbf{z}, \theta)\mathbf{C}^{-1} \quad (1.65)$$

However, we have only \mathbf{k} , the z axis of the frame \mathbf{C} . By expanding equation 1.65 we will discover that $\mathbf{C}\mathbf{Rot}(\mathbf{z}, \theta)\mathbf{C}^{-1}$ is a function of \mathbf{k} only.

Multiplying $\mathbf{Rot}(\mathbf{z}, \theta)$ on the right by \mathbf{C}^{-1} we obtain

$$\begin{aligned} \mathbf{Rot}(\mathbf{z}, \theta)\mathbf{C}^{-1} &= \begin{bmatrix} \cos\theta & -\sin\theta & 0 & 0 \\ \sin\theta & \cos\theta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} n_x & n_y & n_z & 0 \\ o_x & o_x & o_z & 0 \\ a_x & a_y & a_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \\ &= \begin{bmatrix} n_x \cos\theta - o_x \sin\theta & n_y \cos\theta - o_y \sin\theta & n_z \cos\theta - o_z \sin\theta & 0 \\ n_x \sin\theta + o_x \cos\theta & n_y \sin\theta + o_y \cos\theta & n_z \sin\theta + o_z \cos\theta & 0 \\ a_x & a_y & a_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \end{aligned} \quad (1.66)$$

premultiplying by

$$\mathbf{C} = \begin{bmatrix} n_x & o_x & a_x & 0 \\ n_y & o_y & a_y & 0 \\ n_z & o_z & a_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.67)$$

we obtain $\mathbf{C}\mathbf{Rot}(\mathbf{z}, \theta)\mathbf{C}^{-1}$

$$\begin{bmatrix} n_x n_x \cos \theta - n_x o_x \sin \theta + n_x o_x \sin \theta + o_x o_x \cos \theta + a_x a_x \\ n_y n_x \cos \theta - n_y o_x \sin \theta + n_x o_y \sin \theta + o_x o_y \cos \theta + a_y a_x \\ n_z n_x \cos \theta - n_z o_x \sin \theta + n_x o_z \sin \theta + o_x o_z \cos \theta + a_z a_x \\ 0 \\ n_x n_y \cos \theta - n_x o_y \sin \theta + n_y o_x \sin \theta + o_y o_x \cos \theta + a_x a_y \\ n_y n_y \cos \theta - n_y o_y \sin \theta + n_y o_y \sin \theta + o_y o_y \cos \theta + a_y a_y \\ n_z n_y \cos \theta - n_z o_y \sin \theta + n_y o_z \sin \theta + o_y o_z \cos \theta + a_z a_y \\ 0 \\ n_x n_z \cos \theta - n_x o_z \sin \theta + n_z o_x \sin \theta + o_z o_x \cos \theta + a_x a_z \\ n_y n_z \cos \theta - n_y o_z \sin \theta + n_z o_y \sin \theta + o_z o_y \cos \theta + a_y a_z \\ n_z n_z \cos \theta - n_z o_z \sin \theta + n_z o_z \sin \theta + o_z o_z \cos \theta + a_z a_z \\ 0 \end{bmatrix} \quad (1.68)$$

Simplifying, using the following relationships:

the dot product of any row or column of \mathbf{C} with any other row or column is zero, as the vectors are orthogonal;

the dot product of any row or column of \mathbf{C} with itself is $\mathbf{1}$ as the vectors are of unit magnitude;

the z unit vector is the vector cross product of the x and y vectors or

$$\mathbf{a} = \mathbf{n} \times \mathbf{o} \quad (1.69)$$

which has components

$$a_x = n_y o_z - n_z o_y$$

$$a_y = n_z o_x - n_x o_z$$

$$a_z = n_x o_y - n_y o_x$$

the versine, abbreviated **vers** θ , is defined as **vers** $\theta = (1 - \cos \theta)$, $k_x = a_x$, $k_y = a_y$ and $k_z = a_z$. We obtain $\mathbf{Rot}(\mathbf{k}, \theta) =$

$$\begin{bmatrix} k_x k_x \text{vers} \theta + \cos \theta & k_y k_x \text{vers} \theta - k_z \sin \theta & k_z k_x \text{vers} \theta + k_y \sin \theta & 0 \\ k_x k_y \text{vers} \theta + k_z \sin \theta & k_y k_y \text{vers} \theta + \cos \theta & k_z k_y \text{vers} \theta - k_x \sin \theta & 0 \\ k_x k_z \text{vers} \theta - k_y \sin \theta & k_y k_z \text{vers} \theta + k_x \sin \theta & k_z k_z \text{vers} \theta + \cos \theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.70)$$

This is an important result and should be thoroughly understood before proceeding further.

From this general rotation transformation we can obtain each of the elementary rotation transforms. For example $\mathbf{Rot}(\mathbf{x}, \theta)$ is $\mathbf{Rot}(\mathbf{k}, \theta)$ where $k_x = 1$, $k_y = 0$, and $k_z = 0$. Substituting these values of \mathbf{k} into Equation 1.70 we obtain

$$\mathbf{Rot}(\mathbf{x}, \theta) = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos\theta & -\sin\theta & 0 \\ 0 & \sin\theta & \cos\theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.71)$$

as before.

Equivalent Angle and Axis of Rotation

Given any arbitrary rotational transformation, we can use Equation 1.70 to obtain an axis about which an equivalent rotation θ is made as follows. Given a rotational transformation \mathbf{R}

$$\mathbf{R} = \begin{bmatrix} n_x & o_x & a_x & 0 \\ n_y & o_y & a_y & 0 \\ n_z & o_z & a_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.72)$$

we may equate \mathbf{R} to $\mathbf{Rot}(\mathbf{k}, \theta)$

$$\begin{bmatrix} n_x & o_x & a_x & 0 \\ n_y & o_y & a_y & 0 \\ n_z & o_z & a_z & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} k_x k_x \text{vers}\theta + \cos\theta & k_y k_x \text{vers}\theta - k_z \sin\theta & k_z k_x \text{vers}\theta + k_y \sin\theta & 0 \\ k_x k_y \text{vers}\theta + k_z \sin\theta & k_y k_y \text{vers}\theta + \cos\theta & k_z k_y \text{vers}\theta - k_x \sin\theta & 0 \\ k_x k_z \text{vers}\theta - k_y \sin\theta & k_y k_z \text{vers}\theta + k_x \sin\theta & k_z k_z \text{vers}\theta + \cos\theta & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.73)$$

Summing the diagonal terms of Equation 1.73 we obtain

$$n_x + o_y + a_z + 1 = k_x^2 \text{vers}\theta + \cos\theta + k_y^2 \text{vers}\theta + \cos\theta + k_z^2 \text{vers}\theta + \cos\theta + 1 \quad (1.74)$$

$$\begin{aligned} n_x + o_y + a_z &= (k_x^2 + k_y^2 + k_z^2) \text{vers}\theta + 3\cos\theta \\ &= 1 + 2\cos\theta \end{aligned} \quad (1.75)$$

and the cosine of the angle of rotation is

$$\cos\theta = \frac{1}{2}(n_x + o_y + a_z - 1) \quad (1.76)$$

Differencing pairs of off-diagonal terms in Equation 1.73 we obtain

$$o_z - a_y = 2k_x \sin \theta \quad (1.77)$$

$$a_x - n_z = 2k_y \sin \theta \quad (1.78)$$

$$n_y - o_x = 2k_z \sin \theta \quad (1.79)$$

Squaring and adding Equations 1.77-1.79 we obtain an expression for $\sin \theta$

$$(o_z - a_y)^2 + (a_x - n_z)^2 + (n_y - o_x)^2 = 4\sin^2 \theta \quad (1.80)$$

and the sine of the angle of rotation is

$$\sin \theta = \pm \frac{1}{2} \sqrt{(o_z - a_y)^2 + (a_x - n_z)^2 + (n_y - o_x)^2} \quad (1.81)$$

We may define the rotation to be positive about the vector \mathbf{k} such that $0 \leq \theta \leq 180^\circ$. In this case the $+$ sign is appropriate in Equation 1.81 and thus the angle of rotation θ is uniquely defined as

$$\tan \theta = \frac{\sqrt{(o_z - a_y)^2 + (a_x - n_z)^2 + (n_y - o_x)^2}}{(n_x + o_y + a_z - 1)} \quad (1.82)$$

The components of \mathbf{k} may be obtained from Equations 1.77-1.79 as

$$k_x = \frac{o_z - a_y}{2\sin \theta} \quad (1.83)$$

$$k_y = \frac{a_x - n_z}{2\sin \theta} \quad (1.84)$$

$$k_z = \frac{n_y - o_x}{2\sin \theta} \quad (1.85)$$

When the angle of rotation is very small, the axis of rotation is physically not well defined due to the small magnitude of both numerator and denominator in Equations 1.83-1.85. If the resulting angle is small, the vector \mathbf{k} should be renormalized to ensure that $|\mathbf{k}| = 1$. When the angle of rotation approaches 180° the vector \mathbf{k} is once again poorly defined by Equation 1.83-1.85 as the magnitude of the sine is again decreasing. The axis of rotation is, however, physically well defined in this case. When $\theta < 150^\circ$, the denominator of Equations 1.83-1.85 is less than 1. As the angle increases to 180° the rapidly decreasing magnitude of both numerator and denominator leads to considerable inaccuracies in the determination of \mathbf{k} . At $\theta = 180^\circ$, Equations 1.83-1.85 are of the form $0/0$, yielding no information at all about a physically well defined vector \mathbf{k} . If the angle of rotation is greater than 90° , then we must follow a different approach in determining \mathbf{k} . Equating the diagonal elements of Equation 1.73 we obtain

$$k_x^2 \cos \theta + \cos \theta = n_x \quad (1.86)$$

$$k_y^2 \text{vers}\theta + \cos\theta = o_y \quad (1.87)$$

$$k_z^2 \text{vers}\theta + \cos\theta = a_z \quad (1.88)$$

Substituting for $\cos\theta$ and $\text{vers}\theta$ from Equation 1.76 and solving for the elements of \mathbf{k} we obtain further

$$k_x = \pm \sqrt{\frac{n_x - \cos\theta}{1 - \cos\theta}} \quad (1.89)$$

$$k_y = \pm \sqrt{\frac{o_y - \cos\theta}{1 - \cos\theta}} \quad (1.90)$$

$$k_z = \pm \sqrt{\frac{a_z - \cos\theta}{1 - \cos\theta}} \quad (1.91)$$

The largest component of \mathbf{k} defined by Equations 1.89-1.91 corresponds to the most positive component of n_x , o_y , and a_z . For this largest element, the sign of the radical can be obtained from Equations 1.77-1.79. As the sine of the angle of rotation θ must be positive, then the sign of the component of \mathbf{k} defined by Equations 1.77-1.79 must be the same as the sign of the left hand side of these equations. Thus we may combine Equations 1.89-1.91 with the information contained in Equations 1.77-1.79 as follows

$$k_x = \text{sgn}(o_z - a_y) \sqrt{\frac{(n_x - \cos\theta)}{1 - \cos\theta}} \quad (1.92)$$

$$k_y = \text{sgn}(a_x - n_z) \sqrt{\frac{(o_y - \cos\theta)}{1 - \cos\theta}} \quad (1.93)$$

$$k_z = \text{sgn}(n_y - o_x) \sqrt{\frac{(a_z - \cos\theta)}{1 - \cos\theta}} \quad (1.94)$$

where $\text{sgn}(e) = +1$ if $e \geq 0$ and $\text{sgn}(e) = -1$ if $e \leq 0$.

Only the largest element of \mathbf{k} is determined from Equations 1.92-1.94, corresponding to the most positive element of n_x , o_y , and a_z . The remaining elements are more accurately determined by the following equations formed by summing pairs of off-diagonal elements of Equation 1.73

$$n_y + o_x = 2k_x k_y \text{vers}\theta \quad (1.95)$$

$$o_z + a_y = 2k_y k_z \text{vers}\theta \quad (1.96)$$

$$n_z + a_x = 2k_z k_x \text{vers}\theta \quad (1.97)$$

If k_x is largest then

$$k_y = \frac{n_y + o_x}{2k_x \text{vers}\theta} \quad \text{from Equation 1.95} \quad (1.98)$$

$$k_z = \frac{a_x + n_z}{2k_x \text{vers}\theta} \quad \text{from Equation 1.97} \quad (1.99)$$

If k_y is largest then

$$k_x = \frac{n_y + o_x}{2k_y \text{vers}\theta} \quad \text{from Equation 1.95} \quad (1.100)$$

$$k_z = \frac{o_z + a_y}{2k_y \text{vers}\theta} \quad \text{from Equation 1.96} \quad (1.101)$$

If k_z is largest then

$$k_x = \frac{a_x + n_z}{2k_z \text{vers}\theta} \quad \text{from Equation 1.97} \quad (1.102)$$

$$k_y = \frac{o_z + a_y}{2k_z \text{vers}\theta} \quad \text{from Equation 1.96} \quad (1.103)$$

Example 1.1

Determine the equivalent axis and angle of rotation for the matrix given in Equations 1.41

$$\mathbf{Rot}(\mathbf{y}, 90)\mathbf{Rot}(\mathbf{z}, 90) = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.104)$$

We first determine $\cos \theta$ from Equation 1.76

$$\cos \theta = \frac{1}{2}(0 + 0 + 0 - 1) = -\frac{1}{2} \quad (1.105)$$

and $\sin \theta$ from Equation 1.81

$$\sin \theta = \frac{1}{2}\sqrt{(1-0)^2 + (1-0)^2 + (1-0)^2} = \frac{\sqrt{3}}{2} \quad (1.106)$$

Thus

$$\theta = \tan^{-1} \left(\frac{\frac{\sqrt{3}}{2}}{-\frac{1}{2}} \right) = 120^\circ \quad (1.107)$$

As $\theta > 90$, we determine the largest component of \mathbf{k} corresponding to the largest element on the diagonal. As all diagonal elements are equal in this example we may pick any one. We will pick k_x given by Equation 1.92

$$k_x = + \sqrt{(0 + \frac{1}{2}) / (1 + \frac{1}{2})} = \frac{1}{\sqrt{3}} \quad (1.108)$$

As we have determined k_x we may now determine k_y and k_z from Equations 1.98 and 1.99, respectively

$$k_y = \frac{1+0}{\sqrt{3}} = \frac{1}{\sqrt{3}} \quad (1.109)$$

$$k_z = \frac{1+0}{\sqrt{3}} = \frac{1}{\sqrt{3}} \quad (1.110)$$

In summary, then

$$\mathbf{Rot}(\mathbf{y}, 90)\mathbf{Rot}(\mathbf{z}, 90) = \mathbf{Rot}(\mathbf{k}, 120) \quad (1.111)$$

where

$$\mathbf{k} = \frac{1}{\sqrt{3}}\mathbf{i} + \frac{1}{\sqrt{3}}\mathbf{j} + \frac{1}{\sqrt{3}}\mathbf{k} \quad (1.112)$$

Any combination of rotations is always equivalent to a single rotation about some axis \mathbf{k} by an angle θ , an important result that we will make use of later.

Stretching and Scaling

A transform \mathbf{T}

$$\mathbf{T} = \begin{bmatrix} a & 0 & 0 & 0 \\ 0 & b & 0 & 0 \\ 0 & 0 & c & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.113)$$

will stretch objects uniformly along the x axis by a factor a , along the y axis by a factor b , and along the z axis by a factor c . Consider any point on an object $x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$; its transform is

$$\begin{bmatrix} ax \\ by \\ cz \\ 1 \end{bmatrix} = \begin{bmatrix} a & 0 & 0 & 0 \\ 0 & b & 0 & 0 \\ 0 & 0 & c & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} \quad (1.114)$$

indicating stretching as stated. Thus a cube could be transformed into a rectangular parallelepiped by such a transform.

The Axiom code to perform this scale change is:

```

— scale —

scale(scalex, scaley, scalez) ==
matrix(
  [[scalex, 0, 0, 0],
   [0, scaley, 0, 0],
   [0, 0, scalez, 0],
   [0, 0, 0, 1]])

```

The transform \mathbf{S} where

$$\mathbf{S} = \begin{bmatrix} s & 0 & 0 & 0 \\ 0 & s & 0 & 0 \\ 0 & 0 & s & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1.115)$$

will scale any object by the factor s .

Perspective Transformations

Consider the image formed of an object by a simple lens.

The axis of the lens is along the y axis for convenience. An object point x, y, z is imaged at x', y', z' if the lens has a focal length f (f is considered positive). y' represents the image distance and varies with object distance y . If we plot points on a plane perpendicular to the y axis located at y' (the film plane in a camera), then a perspective image is formed.

We will first obtain values of x' , y' , and z' , then introduce a perspective transformation and show that the same values are obtained.

Based on the fact that a ray passing through the center of the lens is undeviated we may write

$$\frac{z}{y} = \frac{z'}{y'} \quad (1.116)$$

$$\text{and } \frac{x}{y} = \frac{x'}{y'} \quad (1.117)$$

Based on the additional fact that a ray parallel to the lens axis passes through the focal point f , we may write

$$\frac{z}{f} = \frac{z'}{y' + f} \quad (1.118)$$

$$\text{and } \frac{x}{f} = \frac{x'}{y' + f} \quad (1.119)$$

Notice that x' , y' , and z' are negative and that f is positive. Eliminating y' between Equations 1.116 and 1.118 we obtain

$$\frac{z}{f} = \frac{z'}{\left(\frac{z'y}{z} + f\right)} \quad (1.120)$$

and solving for z' we obtain the result

$$z' = \frac{z}{\left(1 - \frac{y}{f}\right)} \quad (1.121)$$

Working with Equations 1.117 and 1.119 we can similarly obtain

$$x' = \frac{x}{\left(1 - \frac{y}{f}\right)} \quad (1.122)$$

In order to obtain the image distance y' we rewrite Equations 1.116 and 1.118 as

$$\frac{z}{z'} = \frac{y}{y'} \quad (1.123)$$

and

$$\frac{z}{z'} = \frac{f}{y' + f} \quad (1.124)$$

thus

$$\frac{y}{y'} = \frac{f}{y' + f} \quad (1.125)$$

and solving for y' we obtain the result

$$y' = \frac{y}{\left(1 - \frac{y}{f}\right)} \quad (1.126)$$

The homogeneous transformation \mathbf{P} which produces the same result is

$$\mathbf{P} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -\frac{1}{f} & 0 & 1 \end{bmatrix} \quad (1.127)$$

as any point $x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$ transforms as

$$\begin{bmatrix} x \\ y \\ z \\ 1 - \frac{y}{f} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -\frac{1}{f} & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} \quad (1.128)$$

The image point x', y', z' , obtained by dividing through by the weight factor $(1 - \frac{y}{f})$, is

$$\frac{x}{(1 - \frac{y}{f})} \mathbf{i} + \frac{y}{(1 - \frac{y}{f})} \mathbf{j} + \frac{z}{(1 - \frac{y}{f})} \mathbf{k} \quad (1.129)$$

This is the same result that we obtained above.

A transform similar to \mathbf{P} but with $-\frac{1}{f}$ at the bottom of the first column produces a perspective transformation along the x axis. If the $-\frac{1}{f}$ term is in the third column then the projection is along the z axis.

Transform Equations

We will frequently be required to deal with transform equations in which a coordinate frame is described in two or more ways. A manipulator is positioned with respect to base coordinates by a transform \mathbf{Z} . The end of the manipulator is described by a transform ${}^Z\mathbf{T}_6$, and the end effector is described by ${}^{T_6}\mathbf{E}$. An object is positioned with respect to base coordinates by a transform \mathbf{B} , and finally the manipulator end effector is positioned with respect to the object by ${}^B\mathbf{G}$. We have two descriptions of the position of the end effector, one with respect to the object and one with respect to the manipulator. As both positions are the same, we may equate the two descriptions

$$\mathbf{Z} {}^Z\mathbf{T}_6 {}^{T_6}\mathbf{E} = \mathbf{B} {}^B\mathbf{G} \quad (1.130)$$

If we wish to solve Equation 1.130 for the manipulator transform \mathbf{T}_6 we must premultiply Equation 1.130 by \mathbf{Z}^{-1} and postmultiply by \mathbf{E}^{-1} to obtain

$$\mathbf{T}_6 = \mathbf{Z}^{-1} \mathbf{B} \mathbf{G} \mathbf{E}^{-1} \quad (1.131)$$

As a further example, consider that the position of the object \mathbf{B} is unknown, but that the manipulator is moved such that the end effector is positioned over the object correctly. We may then solve for \mathbf{B} from Equation 1.130 by postmultiplying by \mathbf{G}^{-1} .

$$\mathbf{B} = \mathbf{Z} \mathbf{T}_6 \mathbf{E} \mathbf{G}^{-1} \quad (1.133)$$

Summary

Homogeneous transformations may be readily used to describe the positions and orientations of coordinate frames in space. If a coordinate frame is embedded in an object then the position and orientation of the object are also readily described.

The description of object A in terms of object B by means of a homogeneous transformation may be inverted to obtain the description of object B in terms of object A. This is not a property of a simple vector description of the relative displacement of one object with respect to another.

Transformations may be interpreted as a product of rotation and translation transformations. If they are interpreted from left to right, then the rotations and translations are in terms of the currently defined coordinate frame. If they are interpreted from right to left, then the rotations and translations are described with respect to the reference coordinate frame.

Homogeneous transformations describe coordinate frames in terms of rectangular components, which are the sines and cosines of angles. This description may be related to rotations in which case the description is in terms of a vector and angle of rotation.

4x4 Matrices for coordinate transformations

This package contains functions to create 4x4 matrices useful for rotating and transforming coordinate systems. These matrices are useful for graphics and robotics. (Reference: Robot Manipulators Richard Paul MIT Press 1981)

A Denavit-Hartenberg Matrix is a 4x4 Matrix of the form:

```
nx ox ax px
ny oy ay py
nz oz az pz
```

$\begin{pmatrix} 0 & 0 & 0 & 1 \\ \vdots & \vdots & \vdots & \vdots \end{pmatrix}$
 where n , o , and a are the direction cosines

— Dequeue.help —

=====

Dequeue examples

=====

A Dequeue is a double-ended queue so elements can be added to either end.

Here we create an dequeue of integers from a list. Notice that the order in the list is the order in the dequeue.

```

a:Dequeue INT:= dequeue [1,2,3,4,5]
[1,2,3,4,5]

```

We can remove the top of the dequeue using dequeue!:

```

dequeue! a
1

```

Notice that the use of dequeue! is destructive (destructive operations in Axiom usually end with ! to indicate that the underlying data structure is changed).

```

a
[2,3,4,5]

```

The extract! operation is another name for the dequeue! operation and has the same effect. This operation treats the dequeue as a BagAggregate:

```

extract! a
2

```

and you can see that it also has destructively modified the dequeue:

```

a

```

```
[3,4,5]
```

Next we use `enqueue!` to add a new element to the end of the dequeue:

```
enqueue!(9,a)
9
```

Again, the `enqueue!` operation is destructive so the dequeue is changed:

```
a
[3,4,5,9]
```

Another name for `enqueue!` is `insert!`, which treats the dequeue as a `BagAggregate`:

```
insert!(8,a)
[3,4,5,9,8]
```

and it modifies the dequeue:

```
a
[3,4,5,9,8]
```

The `front` operation returns the item at the front of the dequeue:

```
front a
3
```

The `back` operation returns the item at the back of the dequeue:

```
back a
8
```

The `bottom!` operation returns the item at the back of the dequeue:

```
bottom! a
8
```

and it modifies the dequeue:

```
a
[3,4,5,9]
```

The `depth` function returns the number of elements in the dequeue:

```
depth a
4
```

The `height` function returns the number of elements in the dequeue:

```
height a
4
```

The insertBottom! function adds the element at the end:

```
insertBottom!(6,a)
6
```

and it modifies the dequeue:

```
a
[3,4,5,9,6]
```

The extractBottom! function removes the element at the end:

```
extractBottom! a
6
```

and it modifies the dequeue:

```
a
[3,4,5,9]
```

The insertTop! function adds the element at the top:

```
insertTop!(7,a)
7
```

and it modifies the dequeue:

```
a
[7,3,4,5,9]
```

The extractTop! function adds the element at the top:

```
extractTop! a
7
```

and it modifies the dequeue:

```
a
[3,4,5,9]
```

The top function returns the top element:

```
top a
3
```

and it does not modifies the dequeue:

```
a
  [3,4,5,9]
```

The `top!` function returns the top element:

```
top! a
  3
```

and it modifies the dequeue:

```
a
  [4,5,9]
```

The `reverse!` operation destructively reverses the elements of the dequeue:

```
reverse! a
  [9,5,4]
```

The `rotate!` operation moves the top element to the bottom:

```
rotate! a
  [5,4,9]
```

The `inspect` function returns the top of the dequeue without modification, viewed as a `BagAggregate`:

```
inspect a
  5
```

The `empty?` operation returns true only if there are no element on the dequeue, otherwise it returns false:

```
empty? a
  false
```

The `#` (length) operation:

```
#a
  3
```

The `length` operation does the same thing:

```
length a
  3
```

The `less?` predicate will compare the dequeue length to an integer:

```
less?(a,9)
  true
```

The more? predicate will compare the dequeue length to an integer:

```
more?(a,9)
  false
```

The size? operation will compare the dequeue length to an integer:

```
size?(a,#a)
  true
```

and since the last computation must always be true we try:

```
size?(a,9)
  false
```

The parts function will return the dequeue as a list of its elements:

```
parts a
  [5,4,9]
```

If we have a BagAggregate of elements we can use it to construct a dequeue:

```
bag([1,2,3,4,5])$Dequeue(INT)
  [1,2,3,4,5]
```

The empty function will construct an empty dequeue of a given type:

```
b:=empty()$(Dequeue INT)
  []
```

and the empty? predicate allows us to find out if a dequeue is empty:

```
empty? b
  true
```

The sample function returns a sample, empty dequeue:

```
sample()$Dequeue(INT)
  []
```

We can copy a dequeue and it does not share storage so subsequent modifications of the original dequeue will not affect the copy:

```
c:=copy a
  [5,4,9]
```

The eq? function is only true if the lists are the same reference, so even though c is a copy of a, they are not the same:

```
eq?(a,c)
false
```

However, a clearly shares a reference with itself:

```
eq?(a,a)
true
```

But we can compare a and c for equality:

```
(a=c)@Boolean
true
```

and clearly a is equal to itself:

```
(a=a)@Boolean
true
```

and since a and c are equal, they are clearly NOT not-equal:

```
a~=c
false
```

We can use the any? function to see if a predicate is true for any element:

```
any?(x+>(x=4),a)
true
```

or false for every element:

```
any?(x+>(x=11),a)
false
```

We can use the every? function to check every element satisfies a predicate:

```
every?(x+>(x=11),a)
false
```

We can count the elements that are equal to an argument of this type:

```
count(4,a)
1
```

or we can count against a boolean function:

```
count(x+>(x>2),a)
3
```

You can also map a function over every element, returning a new dequeue:

```
map(x+>x+10,a)
[15,14,19]
```

Notice that the original dequeue is unchanged:

```
a
[5,4,9]
```

You can use `map!` to map a function over every element and change the original dequeue since `map!` is destructive:

```
map!(x+>x+10,a)
[15,14,19]
```

Notice that the original dequeue has been changed:

```
a
[15,14,19]
```

The `members` function can also get the element of the dequeue as a list:

```
members a
[15,14,19]
```

and using `member?` we can test if the dequeue holds a given element:

```
member?(14,a)
true
```

=====

DeRhamComplex examples

=====

The domain constructor DeRhamComplex creates the class of differential forms of arbitrary degree over a coefficient ring. The De Rham complex constructor takes two arguments: a ring, coefRing, and a list of coordinate variables.

This is the ring of coefficients.

```
coefRing := Integer
Integer
Type: Domain
```

These are the coordinate variables.

```
lv : List Symbol := [x,y,z]
[x,y,z]
Type: List Symbol
```

This is the De Rham complex of Euclidean three-space using coordinates x, y and z.

```
der := DERHAM(coefRing,lv)
DeRhamComplex(Integer,[x,y,z])
Type: Domain
```

This complex allows us to describe differential forms having expressions of integers as coefficients. These coefficients can involve any number of variables, for example, $f(x,t,r,y,u,z)$. As we've chosen to work with ordinary Euclidean three-space, expressions involving these forms are treated as functions of x, y and z with the additional arguments t, r and u regarded as symbolic constants.

Here are some examples of coefficients.

```
R := Expression coefRing
Expression Integer
Type: Domain

f : R := x**2*y*z-5*x**3*y**2*z**5
      3 2 5      2
- 5x y z + x y z
Type: Expression Integer

g : R := z**2*y*cos(z)-7*sin(x**3*y**2)*z**2
      2      3 2      2
- 7z sin(x y ) + y z cos(z)
Type: Expression Integer

h : R :=x*y*z-2*x**3*y*z**2
      3      2
- 2x y z + x y z
Type: Expression Integer
```

We now define the multiplicative basis elements for the exterior algebra over R.

```
dx : der := generator(1)
```

```

dx
                                     Type: DeRhamComplex(Integer,[x,y,z])

dy : der := generator(2)
dy
                                     Type: DeRhamComplex(Integer,[x,y,z])

dz : der := generator(3)
dz
                                     Type: DeRhamComplex(Integer,[x,y,z])

```

This is an alternative way to give the above assignments.

```

[dx,dy,dz] := [generator(i)$der for i in 1..3]
[dx,dy,dz]
                                     Type: List DeRhamComplex(Integer,[x,y,z])

```

Now we define some one-forms.

```

alpha : der := f*dx + g*dy + h*dz
          3 2          2 3 2          2
          (- 2x y z + x y z)dz + (- 7z sin(x y ) + y z cos(z))dy
+
          3 2 5 2
          (- 5x y z + x y z)dx
                                     Type: DeRhamComplex(Integer,[x,y,z])

beta : der := cos(tan(x*y*z)+x*y*z)*dx + x*dy
          x dy + cos(tan(x y z) + x y z)dx
                                     Type: DeRhamComplex(Integer,[x,y,z])

```

A well-known theorem states that the composition of exteriorDifferential with itself is the zero map for continuous forms. Let's verify this theorem for alpha.

```

exteriorDifferential alpha
          2          3 2          3 2
          (y z sin(z) + 14z sin(x y ) - 2y z cos(z) - 2x z + x z)dy dz
+
          3 2 4 2 2 2
          (25x y z - 6x y z + y z - x y)dx dz
+
          2 2 2 3 2 3 5 2
          (- 21x y z cos(x y ) + 10x y z - x z)dx dy
                                     Type: DeRhamComplex(Integer,[x,y,z])

```

We see a lengthy output of the last expression, but nevertheless, the composition is zero.

```

exteriorDifferential %

```

0

Type: DeRhamComplex(Integer,[x,y,z])

Now we check that exteriorDifferential is a "graded derivation" D,
that is, D satisfies:

$$D(a*b) = D(a)*b + (-1)**degree(a)*a*D(b)$$

```
gamma := alpha * beta
      4 2 2      3 2
      (2x y z - x y z)dy dz + (2x y z - x y z)cos(tan(x y z) + x y z)dx dz
+
      2 3 2      2      4 2 5      3
      ((7z sin(x y ) - y z cos(z))cos(tan(x y z) + x y z) - 5x y z + x y z)dx dy
      Type: DeRhamComplex(Integer,[x,y,z])
```

We try this for the one-forms alpha and beta.

```
exteriorDifferential(gamma) - (exteriorDifferential(alpha)*beta - alpha * exteriorDifferential(beta))
0
      Type: DeRhamComplex(Integer,[x,y,z])
```

Now we define some "basic operators"

```
a : BOP := operator('a)
a
      Type: BasicOperator
```

```
b : BOP := operator('b)
b
      Type: BasicOperator
```

```
c : BOP := operator('c)
c
      Type: BasicOperator
```

We also define some indeterminate one- and two-forms using these operators.

```
sigma := a(x,y,z) * dx + b(x,y,z) * dy + c(x,y,z) * dz
      c(x,y,z)dz + b(x,y,z)dy + a(x,y,z)dx
      Type: DeRhamComplex(Integer,[x,y,z])

theta := a(x,y,z) * dx * dy + b(x,y,z) * dx * dz + c(x,y,z) * dy * dz
      c(x,y,z)dy dz + b(x,y,z)dx dz + a(x,y,z)dx dy
      Type: DeRhamComplex(Integer,[x,y,z])
```

This allows us to get formal definitions for the "gradient" ...

```
totalDifferential(a(x,y,z))$der
```

```

(23)  a (x,y,z)dz + a (x,y,z)dy + a (x,y,z)dx
      ,3          ,2          ,1
      Type: DeRhamComplex(Integer,[x,y,z])
the "curl" ...

exteriorDifferential sigma
(c (x,y,z) - b (x,y,z))dy dz + (c (x,y,z) - a (x,y,z))dx dz
  ,2          ,3          ,1          ,3
+
(b (x,y,z) - a (x,y,z))dx dy
  ,1          ,2
      Type: DeRhamComplex(Integer,[x,y,z])

and the "divergence."

```

```

exteriorDifferential theta
(c (x,y,z) - b (x,y,z) + a (x,y,z))dx dy dz
  ,1          ,2          ,3
      Type: DeRhamComplex(Integer,[x,y,z])

```

Note that the De Rham complex is an algebra with unity. This element 1 is the basis for elements for zero-forms, that is, functions in our space.

```

one : der := 1
1
      Type: DeRhamComplex(Integer,[x,y,z])

```

To convert a function to a function lying in the De Rham complex, multiply the function by "one."

```

g1 : der := a([x,t,y,u,v,z,e]) * one
a(x,t,y,u,v,z,e)
      Type: DeRhamComplex(Integer,[x,y,z])

```

A current limitation of Axiom forces you to write functions with more than four arguments using square brackets in this way.

```

h1 : der := a([x,y,x,t,x,z,y,r,u,x]) * one
a(x,y,x,t,x,z,y,r,u,x)
      Type: DeRhamComplex(Integer,[x,y,z])

```

Now note how the system keeps track of where your coordinate functions are located in expressions.

```

exteriorDifferential g1
a (x,t,y,u,v,z,e)dz + a (x,t,y,u,v,z,e)dy + a (x,t,y,u,v,z,e)dx
  ,6          ,3          ,1
      Type: DeRhamComplex(Integer,[x,y,z])

```

```

exteriorDifferential h1
  a (x,y,x,t,x,z,y,r,u,x)dz
    ,6
+
  (a (x,y,x,t,x,z,y,r,u,x) + a (x,y,x,t,x,z,y,r,u,x))dy
    ,7                                ,2
+
  a (x,y,x,t,x,z,y,r,u,x) + a (x,y,x,t,x,z,y,r,u,x)
    ,10                                ,5
+
  a (x,y,x,t,x,z,y,r,u,x) + a (x,y,x,t,x,z,y,r,u,x)
    ,3                                ,1
*
dx

```

Type: DeRhamComplex(Integer,[x,y,z])

In this example of Euclidean three-space, the basis for the De Rham complex consists of the eight forms: 1, dx, dy, dz, dx*dy, dx*dz, dy*dz, and dx*dy*dz.

```

coefficient(gamma, dx*dy)
  2      3 2      2      4 2 5      3
  (7z sin(x y ) - y z cos(z))cos(tan(x y z) + x y z) - 5x y z + x y z

```

Type: Expression Integer

```

coefficient(gamma, one)
0

```

Type: Expression Integer

```

coefficient(g1,one)
a(x,t,y,u,v,z,e)

```

Type: Expression Integer

=====
DirectProduct examples
=====

```

This type represents the finite direct or cartesian product of an underlying component type. This contrasts with simple vectors in that the members can be viewed as having constant length. Thus many categorical properties can be lifted from the underlying component type. Component extraction operations are provided but no updating operations. Thus new direct product elements can either be created by converting vector elements using the `directProduct` function or by taking appropriate linear combinations of basis vectors provided by the `unitVector` operation.

domain DIRRING DirichletRing

The Dirichlet Ring is the ring of arithmetical functions

$$f : \mathbb{N}_+ \rightarrow R$$

(see http://en.wikipedia.org/wiki/Arithmetic_function) together with the Dirichlet convolution (see http://en.wikipedia.org/wiki/Dirichlet_convolution) as multiplication and component-wise addition. Since we can consider the values an arithmetic functions assumes as the coefficients of a Dirichlet generating series, we call R the coefficient ring of a function.

In general we only assume that the coefficient ring R is a ring. If R happens to be commutative, then so is the Dirichlet ring, and in this case it is even an algebra.

Apart from the operations inherited from those categories, we only provide some convenient coercion functions.

=====
MultivariatePolynomial
DistributedMultivariatePolynomial
HomogeneousDistributedMultivariatePolynomial
GeneralDistributedMultivariatePolynomial
=====

```

DistributedMultivariatePolynomial which is abbreviated as DMP and HomogeneousDistributedMultivariatePolynomial, which is abbreviated as HDMP, are very similar to MultivariatePolynomial except that they are represented and displayed in a non-recursive manner.

```

(d1,d2,d3) : DMP([z,y,x],FRAC INT)
Type: Void

```

The constructor DMP orders its monomials lexicographically while HDMP orders them by total order refined by reverse lexicographic order.

```

d1 := -4*z + 4*y**2*x + 16*x**2 + 1
      2      2
- 4z + 4y x + 16x  + 1
Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

```

```

d2 := 2*z*y**2 + 4*x + 1
      2
2z y  + 4x + 1
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

d3 := 2*z*x**2 - 2*y**2 - x
      2      2
2z x  - 2y  - x
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

```

These constructors are mostly used in Groebner basis calculations.

```

groebner [d1,d2,d3]

      2 2 8 4 8 4 16 4
 2 1 2 2 1 2 2 1

```

$$z^2 y^2 + 2x^2 + \frac{1}{2}, y^2 x^2 + 4x^2 - z + \frac{1}{4}, z^2 x^2 - y^2 - \frac{1}{2}x,$$

$$z^2 - 4y^2 + 2x^2 - \frac{1}{4}z - \frac{3}{2}x]$$

Type: List HomogeneousDistributedMultivariatePolynomial([z,y,x],
Fraction Integer)

GeneralDistributedMultivariatePolynomial is somewhat more flexible in the sense that as well as accepting a list of variables to specify the variable ordering, it also takes a predicate on exponent vectors to specify the term ordering. With this polynomial type the user can experiment with the effect of using completely arbitrary term orderings. This flexibility is mostly important for algorithms such as Groebner basis calculations which can be very sensitive to term ordering.

)abbrev domain DMP DistributedMultivariatePolynomial
++ Author: Barry Trager
++ Description:
++ This type supports distributed multivariate polynomials
++ whose variables are from a user specified list of symbols.
++ The coefficient ring may be non commutative,
++ but the variables are assumed to commute.
++ The term ordering is lexicographic specified by the variable
++ list parameter with the most significant variable first in the list.

DistributedMultivariatePolynomial(vl,R): public == private where
  vl : List Symbol
  R  : Ring
  E  ==> DirectProduct(#vl,NonNegativeInteger)
  OV ==> OrderedVariableList(vl)
  public == PolynomialCategory(R,E,OV) with
    reorder: (% ,List Integer) -> %

```

```

++ reorder(p, perm) applies the permutation perm to the variables
++ in a polynomial and returns the new correctly ordered polynomial

domain DFLOAT DoubleFloat

Greg Vanuxem has added some functionality to allow the user to modify the printed format of floating point numbers. The format of the numbers follows the common lisp format specification for floats. First we include Greg's email to show the use of this feature:

```

PS: For those who use the Doublefloat domain
    there is an another (undocumented) patch that adds a
    lisp format to the DoubleFloat output routine. Copy
    int/algebra/DFLOAT.spad to your working directory,
    patch it, compile it and ")lib" it when necessary.

```

```

(1) -> )boot $useBFasDefault:=false

(SPADLET |$useBFasDefault| NIL)
Value = NIL
(1) -> a:= matrix [ [0.5978,0.2356], [0.4512,0.2355] ]

      +      0.5978      0.2356      +
(1)  |
      +0.4511999999999999  0.2354999999999999+
                                Type: Matrix DoubleFloat

(2) -> )lib DFLOAT
      DoubleFloat is now explicitly exposed in frame initial
      DoubleFloat will be automatically loaded when needed
from /home/greg/Axiom/DFLOAT.nrllib/code
(2) -> doubleFloatFormat("~",4,,F")

      (2)  "~G"
                                Type: String

(3) -> a

      +0.5978  0.2356+
(3)  |
      +0.4512  0.2355+
                                Type: Matrix DoubleFloat

```

So it is clear that he has added a new function called `doubleFloatFormat` which takes a string argument that specifies the common lisp format control string ("`~",4,,F`"). For reference we quote from the common lisp manual [?]. On page 582 we find:

A format directive consists of a tilde (`~`), optional prefix parameters separated by commas, optional colon (`:`) and at-sign (`@`) modifiers, and a single character indicating what kind of directive this is. The alphabetic case of the directive character is ignored. The prefix parameters are generally integers, notated as optionally signed decimal numbers.

X3J13 voted in June 1987 (80) to specify that if both colon and at-sign modifiers are present, they may appear in either order; thus `~:@R` and `~@:R` mean the same thing. However, it is traditional to put the colon first, and all examples in the book put colon before at-signs.

On page 588 we find:

`~F`

Fixed-format floating-point. The next *arg* is printed as a floating point number.

The full form is `~w,d,k,overflowchar,padcharF`. The parameter *w* is the width of the field to be printed; *d* is the number of digits to print after the decimal point; *k* is a scale factor that defaults to zero.

Exactly w characters will be output. First, leading copies of the character *padchar* (which defaults to a space) are printed, if necessary, to pad the field on the left. If the *arg* is negative, then a minus sign is printed; if the *arg* is not negative, then a plus sign is printed if and only if the `@` modifier was specified. Then a sequence of digits, containing a single embedded decimal point, is printed; this represents the magnitude of the value of *arg* times 10^k , rounded to d fractional digits. (When rounding up and rounding down would produce printed values equidistant from the scaled value of *arg*, then the implementation is free to use either one. For example, printing the argument 6.375 using the format `~4.2F` may correctly produce either 6.37 or 6.38.) Leading zeros are not permitted, except that a single zero digit is output before the decimal point if the printed value is less than 1, and this single zero digit is not output after all if $w = d + 1$.

If it is impossible to print the value in the required format in the field of width w , then one of two actions is taken. If the parameter *overflowchar* is specified, then w copies of that parameter are printed instead of the scaled value of *arg*. If the *overflowchar* parameter is omitted, then the scaled value is printed using more than w characters, as many more as may be needed.

If the w parameter is omitted, then the field is of variable width. In effect, a value is chosen for w in such a way that no leading pad characters need to be printed and exactly d characters will follow the decimal point. For example, the directive `~,2F` will print exactly two digits after the decimal point and as many as necessary before the decimal point.

If the parameter d is omitted, then there is no constraint on the number of digits to appear after the decimal point. A value is chosen for d in such a way that as many digits as possible may be printed subject to the width constraint imposed by the parameter w and the constraint that no trailing zero digits may appear in the fraction, except that if the fraction to be printed is zero, then a single zero digit should appear after the decimal point if permitted by the width constraint.

If both w and d are omitted, then the effect is to print the value using ordinary free-format output; `prin1` uses this format for any number whose magnitude is either zero or between 10^{-3} (inclusive) and 10^7 (exclusive).

If w is omitted, then if the magnitude of *arg* is so large (or, if d is also omitted, so small) that more than 100 digits would have to be printed, then an implementation is free, at its discretion, to print the number using exponential notation instead, as if by the directive `~E` (with all parameters of `~E` defaulted, not taking their values from the `~F` directive).

If *arg* is a rational number, then it is coerced to be a **single-float** and then printed. (Alternatively, an implementation is permitted to process a rational number by any other method that has essentially the same behavior but avoids such hazards as loss of precision or overflow because of the coercion. However, note that if w and d are unspecified and the number has no exact decimal representation, for example $1/3$, some precision cutoff must be chosen by the implementation; only a finite number of digits may be printed.)

If *arg* is a complex number or some non-numeric object, then it is printed using the format directive `~wD`, thereby printing it in decimal radix and a minimum field width of *w*. (If it is desired to print each of the real part and imaginary part of a complex number using a `~F` directive, then this must be done explicitly with two `~F` directives and code to extract the two parts of the complex number.)

A key difficulty is creating test suites which generate DoubleFloats. We need to be bit-exact in the results. This can be achieved using the common lisp `integer-decode-float` function. We cover that function in two different ways, with `machineFraction` which translates the results into an Axiom **Fraction(Integer)** and `integerDecode` which just returns a list of the multiple values from the `integer-decode-float` function.

=====

DoubleFloat examples

=====

Axiom provides two kinds of floating point numbers. The domain Float (abbreviation FLOAT) implements a model of arbitrary precision floating point numbers. The domain DoubleFloat (abbreviation DFLOAT) is intended to make available hardware floating point arithmetic in Axiom. The actual model of floating point DoubleFloat that provides is system-dependent. For example, on the IBM system 370 Axiom uses IBM double precision which has fourteen hexadecimal digits of precision or roughly sixteen decimal digits. Arbitrary precision floats allow the user to specify the precision at which arithmetic

operations are computed. Although this is an attractive facility, it comes at a cost. Arbitrary-precision floating-point arithmetic typically takes twenty to two hundred times more time than hardware floating point.

The usual arithmetic and elementary functions are available for DoubleFloat. By default, floating point numbers that you enter into Axiom are of type Float.

```
2.71828
2.71828
Type: Float
```

You must therefore tell Axiom that you want to use DoubleFloat values and operations. The following are some conservative guidelines for getting Axiom to use DoubleFloat.

To get a value of type DoubleFloat, use a target with @, ...

```
2.71828@DoubleFloat
2.71828
Type: DoubleFloat
```

a conversion, ...

```
2.71828 :: DoubleFloat
2.71828
Type: DoubleFloat
```

or an assignment to a declared variable. It is more efficient if you use a target rather than an explicit or implicit conversion.

```
eApprox : DoubleFloat := 2.71828
2.71828
Type: DoubleFloat
```

You also need to declare functions that work with DoubleFloat.

```
avg : List DoubleFloat -> DoubleFloat
Type: Void
```

```
avg l ==
  empty? l => 0 :: DoubleFloat
  reduce(+,l) / #l
Type: Void
```

```
avg []
0.
Type: DoubleFloat
```

```
avg [3.4,9.7,-6.8]
2.1000000000000001
Type: DoubleFloat
```

Use package-calling for operations from DoubleFloat unless the arguments themselves are already of type DoubleFloat.

```
cos(3.1415926)$DoubleFloat
-0.99999999999999856
Type: DoubleFloat
```

```
cos(3.1415926 :: DoubleFloat)
-0.99999999999999856
Type: DoubleFloat
```

By far, the most common usage of DoubleFloat is for functions to be graphed.

You can get the exact machine-specific bits of a DoubleFloat in two ways. The first is to use the integerDecode function to break the DoubleFloat into components.

```
a := -1.0/3.0
-0.3333333333333331
integerDecode a
[6004799503160661,- 54,- 1]
```

This is the mantissa, exact to 54 bits, the power of 2, and the sign. Thus it is:

```
6004799503160661 * 2^-54
```

You can get the same information as a fraction with

```
machineFraction a
6004799503160661
- -----
18014398509481984
```

where the denominator 18014398509481984 is 2^{54}

— domain DFLOAT DoubleFloat —

```

)abbrev domain DFLOAT DoubleFloat
++ Author: Michael Monagan
++ Date Created: January 1988
++ Description:
++ \spadtype{DoubleFloat} is intended to make accessible
++ hardware floating point arithmetic in Axiom, either native double
++ precision, or IEEE. On most machines, there will be hardware support for
++ the arithmetic operations: ++ +, *, / and possibly also the
++ sqrt operation.
++ The operations exp, log, sin, cos, atan are normally coded in
++ software based on minimax polynomial/rational approximations.
++

```

```

++ Some general comments about the accuracy of the operations:
++ the operations +, *, / and sqrt are expected to be fully accurate.
++ The operations exp, log, sin, cos and atan are not expected to be
++ fully accurate. In particular, sin and cos
++ will lose all precision for large arguments.
++
++ The Float domain provides an alternative to the DoubleFloat domain.
++ It provides an arbitrary precision model of floating point arithmetic.
++ This means that accuracy problems like those above are eliminated
++ by increasing the working precision where necessary. \spadtype{Float}
++ provides some special functions such as erf, the error function
++ in addition to the elementary functions. The disadvantage of Float is that
++ it is much more expensive than small floats when the latter can be used.

DoubleFloat(): Join(FloatingPointSystem, DifferentialRing, OpenMath,
  TranscendentalFunctionCategory, SpecialFunctionCategory, _
  ConvertibleTo InputForm) with

  _/ : (%, Integer) -> %
    ++ x / i computes the division from x by an integer i.

  _*_ : (%,%) -> %
    ++ x ** y returns the yth power of x (equal to \spad{exp(y log x)}).

  exp1 : () -> %
    ++ exp1() returns the natural log base \spad{2.718281828...}.

  hash : % -> Integer
    ++ hash(x) returns the hash key for x

  log2 : % -> %
    ++ log2(x) computes the logarithm with base 2 for x.

  log10: % -> %
    ++ log10(x) computes the logarithm with base 10 for x.

  atan : (%,%) -> %
    ++ atan(x,y) computes the arc tangent from x with phase y.

  Gamma: % -> %
    ++ Gamma(x) is the Euler Gamma function.

  Beta : (%,%) -> %
    ++ Beta(x,y) is \spad{Gamma(x) * Gamma(y)/Gamma(x+y)}.

  doubleFloatFormat : String -> String
    ++doubleFloatFormat changes the output format for doublefloats
    ++using lisp format strings

  rationalApproximation: (%, NonNegativeInteger) -> Fraction Integer

```

```

++rationalApproximation(f, n) computes a rational approximation
++r to f with relative error \spad{< 10**(-n)}.

rationalApproximation: (% , NonNegativeInteger, NonNegativeInteger) -> _
    Fraction Integer
++rationalApproximation(f, n, b) computes a rational
++approximation r to f with relative error \spad{< b**(-n)}
++(that is, \spad{|(r-f)/f| < b**(-n)}).

machineFraction : % -> Fraction Integer
++machineFraction(x) returns a bit-exact fraction of the machine
++floating point number using the common lisp integer-decode-float
++function. See Steele, ISBN 0-13-152414-3 p354
++This function can be used to print results which do not depend
++on binary-to-decimal conversions
++
++X a:DFLOAT:=-1.0/3.0
++X machineFraction a

integerDecode : % -> List Integer
++integerDecode(x) returns the multiple values of the common
++lisp integer-decode-float function.
++See Steele, ISBN 0-13-152414-3 p354. This function can be used
++to ensure that the results are bit-exact and do not depend on
++the binary-to-decimal conversions.
++
++X a:DFLOAT:=-1.0/3.0
++X integerDecode a

=====
DoubleFloatMatrix examples
=====
```

This domain creates a lisp simple array of machine doublefloats.
It provides one new function called qnew which takes an integer
that gives the array length.

NOTE: Unlike normal Axiom arrays the DoubleFloatMatrix arrays
are 0-based so the first element is 0. Axiom arrays normally
start at 1.

```

— domain DROPT DrawOption —

```

)abbrev domain DROPT DrawOption
++ Author: Stephen Watt
++ Date Created: 1 March 1990
++ Date Last Updated: 31 Oct 1990, Jim Wen
++ Description:
++ DrawOption allows the user to specify defaults for the
++ creation and rendering of plots.

DrawOption(): Exports == Implementation where
RANGE ==> List Segment Float
UNIT ==> List Float
PAL ==> Palette
POINT ==> Point(DoubleFloat)
SEG ==> Segment Float
SF ==> DoubleFloat
SPACE3 ==> ThreeSpace(DoubleFloat)
VIEWPT ==> Record(theta:SF, phi:SF, scale:SF, scaleX:SF, scaleY:SF, scaleZ:SF, deltaX:SF, deltaY:SF, deltaZ:SF)

Exports ==> SetCategory with
adaptive : Boolean -> %
  
```

```

++ adaptive(b) turns adaptive 2D plotting on if b is true, or off if b is
++ false. This option is expressed in the form \spad{adaptive == b}.
clip : Boolean -> %
++ clip(b) turns 2D clipping on if b is true, or off if b is false.
++ This option is expressed in the form \spad{clip == b}.
viewpoint : VIEWPT -> %
++ viewpoint(vp) creates a viewpoint data structure corresponding to the
++ list of values. The values are interpreted as [theta, phi, scale,
++ scaleX, scaleY, scaleZ, deltaX, deltaY]. This option is expressed
++ in the form \spad{viewpoint == ls}.
title : String -> %
++ title(s) specifies a title for a plot by the indicated string s.
++ This option is expressed in the form \spad{title == s}.
style : String -> %
++ style(s) specifies the drawing style in which the graph will be plotted
++ by the indicated string s. This option is expressed in the
++ form \spad{style == s}.
toScale : Boolean -> %
++ toScale(b) specifies whether or not a plot is to be drawn to scale;
++ if b is true it is drawn to scale, if b is false it is not. This option
++ is expressed in the form \spad{toScale == b}.
clip : List SEG -> %
++ clip([l]) provides ranges for user-defined clipping as specified
++ in the list l. This option is expressed in the form \spad{clip == [l]}.
coordinates : (POINT -> POINT) -> %
++ coordinates(p) specifies a change of coordinate systems of point p.
++ This option is expressed in the form \spad{coordinates == p}.
pointColor : Float -> %
++ pointColor(v) specifies a color, v, for 2D graph points. This option
++ is expressed in the form \spad{pointColor == v}.
pointColor : PAL -> %
++ pointColor(p) specifies a color index for 2D graph points from the
++ spadcolors palette p. This option is expressed in the
++ form \spad{pointColor == p}.
curveColor : Float -> %
++ curveColor(v) specifies a color, v, for 2D graph curves.
++ This option is expressed in the form \spad{curveColor == v}.
curveColor : PAL -> %
++ curveColor(p) specifies a color index for 2D graph curves from the
++ spadcolors palette p.
++ This option is expressed in the form \spad{curveColor == p}.
colorFunction : (SF -> SF) -> %
++ colorFunction(f(z)) specifies the color based upon the z-component of
++ three dimensional plots. This option is expressed in the
++ form \spad{colorFunction == f(z)}.
colorFunction : ((SF,SF) -> SF) -> %
++ colorFunction(f(u,v)) specifies the color for three dimensional plots
++ as a function based upon the two parametric variables. This option
++ is expressed in the form \spad{colorFunction == f(u,v)}.
colorFunction : ((SF,SF,SF) -> SF) -> %

```

```

++ colorFunction(f(x,y,z)) specifies the color for three dimensional
++ plots as a function of x, y, and z coordinates. This option is
++ expressed in the form \spad{colorFunction == f(x,y,z)}.
tubeRadius : Float -> %
++ tubeRadius(r) specifies a radius, r, for a tube plot around a 3D curve;
++ is expressed in the form \spad{tubeRadius == 4}.
range : List SEG -> %
++ range([l]) provides a user-specified range l.
++ This option is expressed in the form \spad{range == [l]}.
range : List Segment Fraction Integer -> %
++ range([i]) provides a user-specified range i.
++ This option is expressed in the form \spad{range == [i]}.
ranges : RANGE -> %
++ ranges(l) provides a list of user-specified ranges l.
++ This option is expressed in the form \spad{ranges == l}.
space : SPACE3 -> %
++ space specifies the space into which we will draw. If none is given
++ then a new space is created.
var1Steps : PositiveInteger -> %
++ var1Steps(n) indicates the number of subdivisions, n, of the first
++ range variable. This option is expressed in the
++ form \spad{var1Steps == n}.
var2Steps : PositiveInteger -> %
++ var2Steps(n) indicates the number of subdivisions, n, of the second
++ range variable. This option is expressed in the
++ form \spad{var2Steps == n}.
tubePoints : PositiveInteger -> %
++ tubePoints(n) specifies the number of points, n, defining the circle
++ which creates the tube around a 3D curve, the default is 6.
++ This option is expressed in the form \spad{tubePoints == n}.
coord : (POINT->POINT) -> %
++ coord(p) specifies a change of coordinates of point p.
++ This option is expressed in the form \spad{coord == p}.
unit : UNIT -> %
++ unit(lf) will mark off the units according to the indicated list lf.
++ This option is expressed in the form \spad{unit == [f1,f2]}.
option : (List %, Symbol) -> Union(Any, "failed")
++ option() is not to be used at the top level;
++ option determines internally which drawing options are indicated in
++ a draw command.
option?: (List %, Symbol) -> Boolean
++ option?() is not to be used at the top level;
++ option? internally returns true for drawing options which are
++ indicated in a draw command, or false for those which are not.

d02bhfAnnaType examples
=====
```

d02bhfAnnaType is a domain of
 OrdinaryDifferentialEquationsInitialValueProblemSolverCategory
 for the NAG routine D02BHF, a ODE routine which uses a Runge-Kutta method
 to solve a system of differential equations. The function measure measures
 the usefulness of the routine D02BHF for the given problem. The function
 ODESolve performs the integration by using
 NagOrdinaryDifferentialEquationsPackage.

This domain provides elementary functions on any Laurent series domain over a field which was constructed from a Taylor series domain. These functions are implemented by calling the corresponding functions on the Taylor series domain. We also

provide 'partial functions' which compute transcendental functions of Laurent series when possible and return "failed" when this is not possible.

Equation examples

The Equation domain provides equations as mathematical objects. These are used, for example, as the input to various solve operations.

Equations are created using the equals symbol, =.

eq1 := 3*x + 4*y = 5
4y + 3x= 5

Type: Equation Polynomial Integer

eq2 := 2*x + 2*y = 3
2y + 2x= 3

Type: Equation Polynomial Integer

The left- and right-hand sides of an equation are accessible using the operations lhs and rhs.

lhs eq1
4y + 3x

Type: Polynomial Integer

rhs eq1
5

Type: Polynomial Integer

Arithmetic operations are supported and operate on both sides of the equation.

eq1 + eq2
6y + 5x= 8

Type: Equation Polynomial Integer

```
eq1 * eq2
      2      2
      8y  + 14x y + 6x = 15
```

Type: Equation Polynomial Integer

```
2*eq2 - eq1
x= 1
```

Type: Equation Polynomial Integer

Equations may be created for any type so the arithmetic operations will be defined only when they make sense. For example, exponentiation is not defined for equations involving non-square matrices.

```
eq1**2
      2      2
      16y  + 24x y + 9x = 25
```

Type: Equation Polynomial Integer

Note that an equals symbol is also used to test for equality of values in certain contexts. For example, $x+1$ and y are unequal as polynomials.

```
if x+1 = y then "equal" else "unequal"
"unequal"
```

Type: String

```
eqpol := x+1 = y
x + 1= y
```

Type: Equation Polynomial Integer

If an equation is used where a Boolean value is required, then it is evaluated using the equality test from the operand type.

```
if eqpol then "equal" else "unequal"
"unequal"
```

Type: String

If one wants a Boolean value rather than an equation, all one has to do is ask!

```
eqpol::Boolean
false
```

Type: Boolean

=====

EqTable examples

=====

The EqTable domain provides tables where the keys are compared using eq?. Keys are considered equal only if they are the same instance of a structure. This is useful if the keys are themselves updatable structures. Otherwise, all operations are the same as for type Table.

The operation table is here used to create a table where the keys are lists of integers.

```
e: EqTable(List Integer, Integer) := table()
table()
Type: EqTable(List Integer,Integer)
```

These two lists are equal according to =, but not according to eq?.

```
l1 := [1,2,3]
[1,2,3]
Type: List PositiveInteger
```

```
l2 := [1,2,3]
[1,2,3]
Type: List PositiveInteger
```

Because the two lists are not eq?, separate values can be stored under each.

```
e.l1 := 111
111
Type: PositiveInteger
```

```
e.l2 := 222
```

222

Type: PositiveInteger

e.l1

```
=====
Exit examples
=====
```

A function that does not return directly to its caller has Exit as its return type. The operation error is an example of one which does not return to its caller. Instead, it causes a return to top-level.

```
n := 0
```

The function gasp is given return type Exit since it is guaranteed never to return a value to its caller.

```
gasp(): Exit ==
  free n
  n := n + 1
  error "Oh no!"
```

The return type of half is determined by resolving the types of the two branches of the if.

```
half(k) ==
  if odd? k then gasp()
  else k quo 2
```

Because gasp has the return type Exit, the type of if in half is resolved to be Integer.

```
half 4
```

```
half 3
```

```
n

=====

Expression examples

=====

Expression is a constructor that creates domains whose objects can have very general symbolic forms. Here are some examples:

This is an object of type Expression Integer.

```
sin(x) + 3*cos(x)**2
```

This is an object of type Expression Float.

```
tan(x) - 3.45*x
```

This object contains symbolic function applications, sums, products, square roots, and a quotient.

```
(tan sqrt 7 - sin sqrt 11)**2 / (4 - cos(x - y))
```

As you can see, Expression actually takes an argument domain. The coefficients of the terms within the expression belong to the argument domain. Integer and Float, along with Complex Integer and Complex Float are the most common coefficient domains.

The choice of whether to use a Complex coefficient domain or not is important since Axiom can perform some simplifications on real-valued objects

```
log(exp x)@Expression(Integer)
```

... which are not valid on complex ones.

```
log(exp x)@Expression(Complex Integer)
```

Many potential coefficient domains, such as AlgebraicNumber, are not usually used because Expression can subsume them.

```
sqrt 3 + sqrt(2 + sqrt(-5))
```

```
% :: Expression Integer
```

Note that we sometimes talk about "an object of type Expression." This is not really correct because we should say, for example, "an object of type Expression Integer" or "an object of type Expression Float." By a similar abuse of language, when we refer to an "expression" in this section we will mean an object of type Expression R for some domain R.

The Axiom documentation contains many examples of the use of Expression. For the rest of this section, we'll give you some pointers to those examples plus give you some idea of how to manipulate expressions.

It is important for you to know that Expression creates domains that have category Field. Thus you can invert any non-zero expression and you shouldn't expect an operation like factor to give you much information. You can imagine expressions as being represented as quotients of "multivariate" polynomials where the "variables" are kernels. A kernel can either be a symbol such as x or a symbolic function application like sin(x + 4). The second example is actually a nested kernel since the argument to sin contains the kernel x.

```
height mainKernel sin(x + 4)
```

Actually, the argument to sin is an expression, and so the structure of Expression is recursive. See Kernel which demonstrates how to

extract the kernels in an expression.

Use the HyperDoc Browse facility to see what operations are applicable to expression. At the time of this writing, there were 262 operations with 147 distinct name in Expression Integer. For example, numer and denom extract the numerator and denominator of an expression.

```
e := (sin(x) - 4)**2 / ( 1 - 2*y*sqrt(- y) )
```

```
numer e
```

```
denom e
```

Use D to compute partial derivatives.

```
D(e, x)
```

```
D(e, [x, y], [1, 2])
```

When an expression involves no ‘symbol kernels’ (for example, x), it may be possible to numerically evaluate the expression.

If you suspect the evaluation will create a complex number, use complexNumeric.

```
complexNumeric(cos(2 - 3*i))
```

If you know it will be real, use numeric.

```
numeric(tan 3.8)
```

The numeric operation will display an error message if the evaluation yields a value with a non-zero imaginary part. Both of these operations have an optional second argument n which specifies that the accuracy of the approximation be up to n decimal places.

When an expression involves no "symbolic application" kernels, it may be possible to convert it a polynomial or rational function in the variables that are present.

```
e2 := cos(x**2 - y + 3)
```

```
e3 := asin(e2) - %pi/2
```

```
e3 :: Polynomial Integer
```

This also works for the polynomial types where specific variables and their ordering are given.

```
e3 :: DMP([x, y], Integer)
```

Finally, a certain amount of simplification takes place as expressions are constructed.

```
sin %pi
```

```
cos(%pi / 4)
```

For simplifications that involve multiple terms of the expression, use `simplify`.

```
tan(x)**6 + 3*tan(x)**4 + 3*tan(x)**2 + 1
```

```
simplify %
```

=====
ExponentialOfUnivariatePuisseuxSeries examples
=====

```

`ExponentialOfUnivariatePuisseuxSeries` is a domain used to represent essential singularities of functions. An object in this domain is a function of the form $\exp(f(x))$, where $f(x)$ is a Puiseux series with no terms of non-negative degree. Objects are ordered according to order of singularity, with functions which tend more rapidly to zero or infinity considered to be larger. Thus, if $\text{order}(f(x)) < \text{order}(g(x))$, i.e. the first non-zero term of $f(x)$ has lower degree than the first non-zero term of $g(x)$, then $\exp(f(x)) > \exp(g(x))$. If $\text{order}(f(x)) = \text{order}(g(x))$, then the ordering is essentially random. This domain is used in computing limits involving functions with essential singularities.

)abbrev domain EXPUPXS ExponentialOfUnivariatePuisseuxSeries
++ Author: Clifton J. Williamson
++ Date Created: 4 August 1992
++ Date Last Updated: 27 August 1992
++ References:
++ Description:
++ ExponentialOfUnivariatePuisseuxSeries is a domain used to represent
++ essential singularities of functions. An object in this domain is a
++ function of the form \spad{exp(f(x))}, where \spad{f(x)} is a Puiseux
++ series with no terms of non-negative degree. Objects are ordered
++ according to order of singularity, with functions which tend more
++ rapidly to zero or infinity considered to be larger. Thus, if
++ \spad{order(f(x)) < order(g(x))}, i.e. the first non-zero term of
++ \spad{f(x)} has lower degree than the first non-zero term of \spad{g(x)},
++ then \spad{exp(f(x)) > exp(g(x))}. If \spad{order(f(x)) = order(g(x))},
++ then the ordering is essentially random. This domain is used
++ in computing limits involving functions with essential singularities.

=====
ExtAlgBasis examples
=====
```

A domain used in the construction of the exterior algebra on a set X over a ring R . This domain represents the set of all ordered subsets of the set X , assumed to be in correspondance with $\{1,2,3, \dots\}$. The ordered subsets are themselves ordered lexicographically and are in bijective correspondance with an ordered basis of the exterior algebra. In this domain we are dealing strictly with the exponents of basis elements which can only be 0 or 1. Thus we really have $L(\{0,1\})$.

The multiplicative identity element of the exterior algebra corresponds to the empty subset of X . A coerce from List Integer to an ordered basis element is provided to allow the convenient input of expressions. Another exported function forgets the ordered structure and simply returns the list corresponding to an ordered subset.

=====

Factored examples

=====

Factored creates a domain whose objects are kept in factored form as long as possible. Thus certain operations like * (multiplication) and gcd are relatively easy to do. Others, such as addition, require somewhat more work, and the result may not be completely factored unless the argument domain R provides a factor operation. Each object consists of a unit and a list of factors, where each factor consists of a member of R (the base), an exponent, and a flag indicating what is known about the base. A flag may be one of "nil", "sqfr", "irred" or "prime", which mean that nothing is known about the base, it is square-free, it is irreducible, or it is prime, respectively. The current restriction to factored objects of integral domains allows simplification to be performed without worrying about multiplication order.

=====

Decomposing Factored Objects

=====

In this section we will work with a factored integer.

```

g := factor(4312)
      3 2
      2 7 11

```

Type: Factored Integer

Let's begin by decomposing g into pieces. The only possible units for integers are 1 and -1.

```

unit(g)
      1

```

Type: PositiveInteger

There are three factors.

```

numberOfFactors(g)
3
                                Type: PositiveInteger

```

We can make a list of the bases, ...

```

[nthFactor(g,i) for i in 1..numberOfFactors(g)]
[2,7,11]
                                Type: List Integer

```

and the exponents, ...

```

[nthExponent(g,i) for i in 1..numberOfFactors(g)]
[3,2,1]
                                Type: List Integer

```

and the flags. You can see that all the bases (factors) are prime.

```

[nthFlag(g,i) for i in 1..numberOfFactors(g)]
["prime","prime","prime"]
                                Type: List Union("nil","sqfr","irred","prime")

```

A useful operation for pulling apart a factored object into a list of records of the components is `factorList`.

```

factorList(g)
[[flg= "prime",fctr= 2,xpnt= 3], [flg= "prime",fctr= 7,xpnt= 2],
 [flg= "prime",fctr= 11,xpnt= 1]]
                                Type: List Record(flg: Union("nil","sqfr","irred","prime"),
                                fctr: Integer,xpnt: Integer)

```

If you don't care about the flags, use `factors`.

```

factors(g)
[[factor= 2,exponent= 3],[factor= 7,exponent= 2],[factor= 11,exponent= 1]]
                                Type: List Record(factor: Integer,exponent: Integer)

```

Neither of these operations returns the unit.

```

first(%).factor
2
                                Type: PositiveInteger

```

Expanding Factored Objects

Recall that we are working with this factored integer.

```

g := factor(4312)

```

```

3 2
2 7 11

```

Type: Factored Integer

To multiply out the factors with their multiplicities, use `expand`.

```

expand(g)
4312

```

Type: PositiveInteger

If you would like, say, the distinct factors multiplied together but with multiplicity one, you could do it this way.

```

reduce(*,[t.factor for t in factors(g)])
154

```

Type: PositiveInteger

=====

Arithmetic with Factored Objects

=====

We're still working with this factored integer.

```

g := factor(4312)
3 2
2 7 11

```

Type: Factored Integer

We'll also define this factored integer.

```

f := factor(246960)
4 2 3
2 3 5 7

```

Type: Factored Integer

Operations involving multiplication and division are particularly easy with factored objects.

```

f * g
7 2 5
2 3 5 7 11

```

Type: Factored Integer

```

f**500
2000 1000 500 1500
2 3 5 7

```

Type: Factored Integer

```

gcd(f,g)
3 2

```

```
2 7
Type: Factored Integer
```

```
lcm(f,g)
  4 2 3
  2 3 5 7 11
Type: Factored Integer
```

If we use addition and subtraction things can slow down because we may need to compute greatest common divisors.

```
f + g
  3 2
  2 7 641
Type: Factored Integer
```

```
f - g
  3 2
  2 7 619
Type: Factored Integer
```

Test for equality with 0 and 1 by using zero? and one?, respectively.

```
zero?(factor(0))
true
Type: Boolean
```

```
zero?(g)
false
Type: Boolean
```

```
one?(factor(1))
true
Type: Boolean
```

```
one?(f)
false
Type: Boolean
```

Another way to get the zero and one factored objects is to use package calling.

```
0$Factored(Integer)
0
Type: Factored Integer
```

```
1$Factored(Integer)
1
Type: Factored Integer
```

```
=====
Creating New Factored Objects
=====
```

The map operation is used to iterate across the unit and bases of a factored object.

The following four operations take a base and an exponent and create a factored object. They differ in handling the flag component.

```
nilFactor(24,2)
      2
     24
                                Type: Factored Integer
```

This factor has no associated information.

```
nthFlag(%,1)
"nil"
                                Type: Union("nil",...)
```

This factor is asserted to be square-free.

```
sqfrFactor(30,2)
      2
     30
                                Type: Factored Integer
```

This factor is asserted to be irreducible.

```
irreducibleFactor(13,10)
      10
     13
                                Type: Factored Integer
```

This factor is asserted to be prime.

```
primeFactor(11,5)
      5
     11
                                Type: Factored Integer
```

A partial inverse to factorList is makeFR.

```
h := factor(-720)
      4 2
     - 2 3 5
                                Type: Factored Integer
```

The first argument is the unit and the second is a list of records as

returned by factorList.

```
h - makeFR(unit(h),factorList(h))
0
Type: Factored Integer
```

=====

Factored Objects with Variables

=====

Some of the operations available for polynomials are also available for factored polynomials.

```
p := (4*x*x-12*x+9)*y*y + (4*x*x-12*x+9)*y + 28*x*x - 84*x + 63
      2      2      2      2
(4x - 12x + 9)y + (4x - 12x + 9)y + 28x - 84x + 63
Type: Polynomial Integer
```

```
fp := factor(p)
      2 2
(2x - 3) (y + y + 7)
Type: Factored Polynomial Integer
```

You can differentiate with respect to a variable.

```
D(p,x)
      2
(8x - 12)y + (8x - 12)y + 56x - 84
Type: Polynomial Integer
```

```
D(fp,x)
      2
4(2x - 3)(y + y + 7)
Type: Factored Polynomial Integer
```

```
numberOfFactors(%)
3
Type: PositiveInteger
```

)abbrev domain FR Factored
++ Author: Robert S. Sutor, J. Grabmeier
++ Date Created: 1985
++ Change History: 21 Jan 1991 (J Grabmeier) 16 Aug 1994 (R S Sutor)
++ Description:
++ \spadtype{Factored} creates a domain whose objects are kept in
++ factored form as long as possible. Thus certain operations like
++ multiplication and gcd are relatively easy to do. Others, like
++ addition require somewhat more work, and unless the argument
++ domain provides a factor function, the result may not be
++ completely factored. Each object consists of a unit and a list of
++ factors, where a factor has a member of R (the "base"), and
++ exponent and a flag indicating what is known about the base. A
++ flag may be one of "nil", "sqfr", "irred" or "prime", which respectively mean
++ that nothing is known about the base, it is square-free, it is
++ irreducible, or it is prime. The current
++ restriction to integral domains allows simplification to be
++ performed without worrying about multiplication order.

```

```

Factored(R: IntegralDomain): Exports == Implementation where
  fUnion ==> Union("nil", "sqfr", "irred", "prime")
  FF      ==> Record(flag: fUnion, fctr: R, xpnt: Integer)
  SRFE    ==> Set(Record(factor:R, exponent:Integer))

Exports ==> Join(IntegralDomain, DifferentialExtension R, Algebra R,
  FullyEvalableOver R, FullyRetractableTo R) with
expand: % -> R
  ++ expand(f) multiplies the unit and factors together, yielding an
  ++ "unfactored" object. Note: this is purposely not called
  ++ \spadfun{coerce} which would cause the interpreter to do this
  ++ automatically.
  ++
  ++X f:=nilFactor(y-x,3)
  ++X expand(f)

exponent: % -> Integer
  ++ exponent(u) returns the exponent of the first factor of
  ++ \spadvar{u}, or 0 if the factored form consists solely of a unit.
  ++
  ++X f:=nilFactor(y-x,3)
  ++X exponent(f)

makeFR : (R, List FF) -> %
  ++ makeFR(unit,listOfFactors) creates a factored object (for
  ++ use by factoring code).
  ++
  ++X f:=nilFactor(x-y,3)
  ++X g:=factorList f
  ++X makeFR(z,g)

factorList : % -> List FF
  ++ factorList(u) returns the list of factors with flags (for
  ++ use by factoring code).
  ++
  ++X f:=nilFactor(x-y,3)
  ++X factorList f

nilFactor: (R, Integer) -> %
  ++ nilFactor(base,exponent) creates a factored object with
  ++ a single factor with no information about the kind of
  ++ base (flag = "nil").
  ++
  ++X nilFactor(24,2)
  ++X nilFactor(x-y,3)

factors: % -> List Record(factor:R, exponent:Integer)
  ++ factors(u) returns a list of the factors in a form suitable
  ++ for iteration. That is, it returns a list where each element

```

```

++ is a record containing a base and exponent. The original
++ object is the product of all the factors and the unit (which
++ can be extracted by \axiom{unit(u)}).
++
++X f:=x*y^3-3*x^2*y^2+3*x^3*y-x^4
++X factors f
++X g:=makeFR(z,factorList f)
++X factors g

++ irreducibleFactor(base,exponent) creates a factored object with
++ a single factor whose base is asserted to be irreducible
++ (flag = "irred").
++
++X a:=irreducibleFactor(3,1)
++X nthFlag(a,1)

nthExponent: (% , Integer) -> Integer
++ nthExponent(u,n) returns the exponent of the nth factor of
++ \spadvar{u}. If \spadvar{n} is not a valid index for a factor
++ (for example, less than 1 or too big), 0 is returned.
++
++X a:=factor 9720000
++X nthExponent(a,2)

nthFactor: (% ,Integer) -> R
++ nthFactor(u,n) returns the base of the nth factor of
++ \spadvar{u}. If \spadvar{n} is not a valid index for a factor
++ (for example, less than 1 or too big), 1 is returned. If
++ \spadvar{u} consists only of a unit, the unit is returned.
++
++X a:=factor 9720000
++X nthFactor(a,2)

nthFlag: (% ,Integer) -> fUnion
++ nthFlag(u,n) returns the information flag of the nth factor of
++ \spadvar{u}. If \spadvar{n} is not a valid index for a factor
++ (for example, less than 1 or too big), "nil" is returned.
++
++X a:=factor 9720000
++X nthFlag(a,2)

numberOfFactors : % -> NonNegativeInteger
++ numberOfFactors(u) returns the number of factors in \spadvar{u}.
++
++X a:=factor 9720000
++X numberOfFactors a

primeFactor: (R,Integer) -> %
++ primeFactor(base,exponent) creates a factored object with

```

```

++ a single factor whose base is asserted to be prime
++ (flag = "prime").
++
++X a:=primeFactor(3,4)
++X nthFlag(a,1)

sqfrFactor: (R,Integer) -> %
++ sqfrFactor(base,exponent) creates a factored object with
++ a single factor whose base is asserted to be square-free
++ (flag = "sqfr").
++
++X a:=sqfrFactor(3,5)
++X nthFlag(a,1)

flagFactor: (R,Integer, fUnion) -> %
++ flagFactor(base,exponent,flag) creates a factored object with
++ a single factor whose base is asserted to be properly
++ described by the information flag.

unit: % -> R
++ unit(u) extracts the unit part of the factorization.
++
++X f:=x*y^3-3*x^2*y^2+3*x^3*y-x^4
++X unit f
++X g:=makeFR(z,factorList f)
++X unit g

unitNormalize: % -> %
++ unitNormalize(u) normalizes the unit part of the factorization.
++ For example, when working with factored integers, this operation will
++ ensure that the bases are all positive integers.

map: (R -> R, %) -> %
++ map(fn,u) maps the function \userfun{fn} across the factors of
++ \spadvar{u} and creates a new factored object. Note: this clears
++ the information flags (sets them to "nil") because the effect of
++ \userfun{fn} is clearly not known in general.
++
++X m(a:Factored Polynomial Integer):Factored Polynomial Integer == a^2
++X f:=x*y^3-3*x^2*y^2+3*x^3*y-x^4
++X map(m,f)

— File.help —

=====

File examples

=====

The File(S) domain provides a basic interface to read and write values of type S in files.

Before working with a file, it must be made accessible to Axiom with the open operation.

```
ifile:File List Integer:=open("/tmp/jazz1","output")
    "jazz1"
                                Type: File List Integer
```

The open function arguments are a FileNam} and a String specifying the mode. If a full pathname is not specified, the current default directory is assumed. The mode must be one of "input" or "output". If it is not specified, "input" is assumed. Once the file has been opened, you can read or write data.

The operations read and write are provided.

```
write!(ifile, [-1,2,3])
    [- 1,2,3]
                                Type: List Integer
```

```
write!(ifile, [10,-10,0,111])
    [10,- 10,0,111]
                                Type: List Integer
```

```
write!(ifile, [7])
    [7]
                                Type: List Integer
```

You can change from writing to reading (or vice versa) by reopening a file.

```
reopen!(ifile, "input")
    "jazz1"
                                Type: File List Integer
```

```
read! ifile
    [- 1,2,3]
                                Type: List Integer
```

```
read! ifile
    [10,- 10,0,111]
                                Type: List Integer
```

The read operation can cause an error if one tries to read more data than is in the file. To guard against this possibility the readIfCan operation should be used.

```
readIfCan! ifile
[7]
Type: Union(List Integer,...)
```

```
readIfCan! ifile
"failed"
Type: Union("failed",...)
```

You can find the current mode of the file, and the file's name.

```
iomode ifile
"input"
Type: String
```

```
name ifile
"jazz1"
Type: FileName
```

When you are finished with a file, you should close it.

```
close! ifile
"jazz1"
Type: File List Integer
```

```
)system rm /tmp/jazz1
```

A limitation of the underlying LISP system is that not all values can be represented in a file. In particular, delayed values containing compiled functions cannot be saved.

— domain **FILE** File —

```

)abbrev domain FILE File
++ Author: Stephen M. Watt, Victor Miller
++ Date Created: 1984
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides a basic model of files to save arbitrary values.
++ The operations provide sequential access to the contents.

File(S:SetCategory): FileCategory(FileName, S) with
  readIfCan_!: % -> Union(S, "failed")
    ++ readIfCan!(f) returns a value from the file f, if possible.
    ++ If f is not open for reading, or if f is at the end of file
    ++ then \spad{"failed"} is the result.

— **FileName.help** —

=====
 FileName examples
 =====

The FileName domain provides an interface to the computer's file system. Functions are provided to manipulate file names and to test properties of files.

The simplest way to use file names in the Axiom interpreter is to rely on conversion to and from strings. The syntax of these strings depends on the operating system.

```

fn: FileName
                                Type: Void

```

On Linux, this is a proper file syntax:

```

fn := "fname.input"
    "fname.input"
                                Type: FileName

```

Although it is very convenient to be able to use string notation for file names in the interpreter, it is desirable to have a portable way of creating and manipulating file names from within programs.

A measure of portability is obtained by considering a file name to consist of three parts: the directory, the name, and the extension.

```

directory fn
    ""
                                Type: String

name fn
    "fname"
                                Type: String

extension fn
    "input"
                                Type: String

```

The meaning of these three parts depends on the operating system. For example, on CMS the file "SPADPROF INPUT M" would have directory "M", name "SPADPROF" and extension "INPUT".

It is possible to create a filename from its parts.

```

fn := filename("/tmp", "fname", "input")
    "/tmp/fname.input"
                                Type: FileName

```

When writing programs, it is helpful to refer to directories via variables.

```

objdir := "/tmp"
    "/tmp"
                                Type: String

fn := filename(objdir, "table", "spad")
    "/tmp/table.spad"
                                Type: FileName

```

If the directory or the extension is given as an empty string, then a default is used. On AIX, the defaults are the current directory and no extension.

```

fn := filename("", "letter", "")
    "letter"
                                Type: FileName

```

Three tests provide information about names in the file system.

The exists? operation tests whether the named file exists.

```
exists? "/etc/passwd"
true
Type: Boolean
```

The operation readable? tells whether the named file can be read. If the file does not exist, then it cannot be read.

```
readable? "/etc/passwd"
true
Type: Boolean
```

```
readable? "/etc/security/passwd"
false
Type: Boolean
```

```
readable? "/ect/passwd"
false
Type: Boolean
```

Likewise, the operation writable? tells whether the named file can be written. If the file does not exist, the test is determined by the properties of the directory.

```
writable? "/etc/passwd"
true
Type: Boolean
```

```
writable? "/dev/null"
true
Type: Boolean
```

```
writable? "/etc/DoesNotExist"
true
Type: Boolean
```

```
writable? "/tmp/DoesNotExist"
true
Type: Boolean
```

The new operation constructs the name of a new writable file. The argument sequence is the same as for filename, except that the name part is actually a prefix for a constructed unique name.

The resulting file is in the specified directory with the given extension, and the same defaults are used.

```
fn := new(objdir, "xxx", "yy")
"/tmp/xxx1419.yy"
```

=====

FiniteFieldCyclicGroup examples

=====

`FiniteFieldCyclicGroup(p,n)` implements a finite field extension of degree n over the prime field with p elements. Its elements are represented by powers of a primitive element, i.e. a generator of the multiplicative (cyclic) group. As primitive element we choose the root of the extension polynomial, which is created by `createPrimitivePoly` from `FiniteFieldPolynomialPackage`. The Zech logarithms are stored in a table of size half of the field size, and use `SingleInteger` for representing field elements, hence, there are restrictions on the size of the field.

=====
FiniteFieldCyclicGroupExtensionByPolynomial examples
=====
```

`FiniteFieldCyclicGroupExtensionByPolynomial(GF,defpol)` implements a finite extension field of the ground field GF. Its elements are represented by powers of a primitive element, i.e. a generator of the multiplicative (cyclic) group. As primitive element we choose the root of the extension polynomial `defpol`, which **MUST** be primitive (user responsibility). Zech logarithms are stored in a table of size half of the field size, and use `SingleInteger` for representing field elements, hence, there are restrictions on the size of the field.

FiniteFieldNormalBasis(p,n) implements a finite extension field of degree n over the prime field with p elements. The elements are represented by coordinate vectors with respect to a normal basis, i.e. a basis consisting of the conjugates (q-powers) of an element, in this case called normal element. This is chosen as a root of the extension polynomial created by createNormalPoly

```

See that its physical length has grown.

```
physicalLength f
10
Type: PositiveInteger
```

Make f grow to have room for 15 elements.

```
physicalLength!(f,15)
[1,2,3,4,5,6,11]
Type: FlexibleArray Integer
```

Concatenate the elements of f to itself. The physical length allows room for three more values at the end.

```
concat!(f,f)
[1,2,3,4,5,6,11,1,2,3,4,5,6,11]
Type: FlexibleArray Integer
```

Use insert! to add an element to the front of a flexible array.

```
insert!(22,f,1)
[22,1,2,3,4,5,6,11,1,2,3,4,5,6,11]
Type: FlexibleArray Integer
```

Create a second flexible array from f consisting of the elements from index 10 forward.

```
g := f(10..)
[2,3,4,5,6,11]
Type: FlexibleArray Integer
```

Insert this array at the front of f.

```
insert!(g,f,1)
[2,3,4,5,6,11,22,1,2,3,4,5,6,11,1,2,3,4,5,6,11]
Type: FlexibleArray Integer
```

Merge the flexible array f into g after sorting each in place.

```
merge!(sort! f, sort! g)
[1,1,2,2,2,2,3,3,3,3,4,4,4,4,5,5,5,5,6,6,6,6,11,11,11,11,22]
Type: FlexibleArray Integer
```

Remove duplicates in place.

```
removeDuplicates! f
[1,2,3,4,5,6,11,22]
Type: FlexibleArray Integer
```

Remove all odd integers.

```
select!(i +-> even? i,f)
[2,4,6,22]
Type: FlexibleArray Integer
```

All these operations have shrunk the physical length of f.

```
physicalLength f
8
Type: PositiveInteger
```

To force Axiom not to shrink flexible arrays call the shrinkable operation with the argument false. You must package call this operation. The previous value is returned.

```
shrinkable(false)$FlexibleArray(Integer)
true
Type: Boolean
```

— domain FARRAY FlexibleArray —

```
)abbrev domain FARRAY FlexibleArray
++ Author: Mark Botch
++ Description:
++ A FlexibleArray is the notion of an array intended to allow for growth
++ at the end only. Hence the following efficient operations
++ \spad{append(x,a)} meaning append item x at the end of the array \spad{a}
++ \spad{delete(a,n)} meaning delete the last item from the array \spad{a}
++ Flexible arrays support the other operations inherited from
++ \spadtype{ExtensibleLinearAggregate}. However, these are not efficient.
++ Flexible arrays combine the \spad{O(1)} access time property of arrays
++ with growing and shrinking at the end in \spad{O(1)} (average) time.
++ This is done by using an ordinary array which may have zero or more
++ empty slots at the end. When the array becomes full it is copied
++ into a new larger (50% larger) array. Conversely, when the array
++ becomes less than 1/2 full, it is copied into a smaller array.
++ Flexible arrays provide for an efficient implementation of many
++ data structures in particular heaps, stacks and sets.
```

```
FlexibleArray(S: Type) == Implementation where
  ARRAYMININDEX ==> 1      -- if you want to change this, be my guest
  Implementation ==> IndexedFlexibleArray(S, ARRAYMININDEX)
-- Join(OneDimensionalArrayAggregate S, ExtensibleLinearAggregate S)

```

domain **Float**

As reported in bug number 4733 (rounding of negative numbers) errors were observed in operations such as

```
-> round(-3.9)
-> truncate(-3.9)
```

The problem is the unexpected behaviour of the shift with negative integer arguments.

```
-> shift(-7,-1)
```

returns -4 while the code here in float expects the value to be -3. shift uses the lisp function ASH 'arithmetic shift left' but the spad code expects an unsigned 'logical' shift. See

http://www.lispworks.com/reference/HyperSpec/Body/f_ash.htm#ash

A new internal function shift2 is defined in terms of shift to compensate for the use of ASH and provide the required function.

It is currently unknown whether the unexpected behaviour of shift for negative arguments will cause bugs in other parts of Axiom.

Float

Axiom provides two kinds of floating point numbers. The domain Float implements a model of arbitrary precision floating point numbers. The domain DoubleFloat is intended to make available hardware floating point arithmetic in Axiom. The actual model of floating point that DoubleFloat provides is system-dependent. For example, on the IBM system 370 Axiom uses IBM double precision which has fourteen hexadecimal digits of precision or roughly sixteen decimal digits. Arbitrary precision floats allow the user to specify the precision at which arithmetic operations are computed. Although this is an attractive facility, it comes at a cost. Arbitrary-precision floating-point arithmetic typically takes twenty to two hundred times more time than hardware floating point.

Introduction to Float

Scientific notation is supported for input and output of floating point numbers. A floating point number is written as a string of digits containing a decimal point optionally followed by the letter "E", and then the exponent.

We begin by doing some calculations using arbitrary precision floats. The default precision is twenty decimal digits.

```
1.234
1.234
                                Type: Float
```

A decimal base for the exponent is assumed, so the number 1.234E2 denotes 1.234×10^2 .

```
1.234E2
123.4
                                Type: Float
```

The normal arithmetic operations are available for floating point numbers.

```
sqrt(1.2 + 2.3 / 3.4 ** 4.5)
1.0996972790 671286226
                                Type: Float
```

===== Conversion Functions =====

You can use conversion to go back and forth between Integer, Fraction Integer and Float, as appropriate.

```
i := 3 :: Float
3.0
                                Type: Float

i :: Integer
3
                                Type: Integer

i :: Fraction Integer
3
                                Type: Fraction Integer
```

Since you are explicitly asking for a conversion, you must take responsibility for any loss of exactness.

```
r := 3/7 :: Float
0.4285714285 7142857143
                                Type: Float
```

```

r :: Fraction Integer
  3
  -
  7

```

Type: Fraction Integer

This conversion cannot be performed: use truncate or round if that is what you intend.

```

r :: Integer
Cannot convert from type Float to Integer for value
0.4285714285 7142857143

```

The operations truncate and round truncate ...

```

truncate 3.6
3.0

```

Type: Float

and round to the nearest integral Float respectively.

```

round 3.6
4.0

```

Type: Float

```

truncate(-3.6)
- 3.0

```

Type: Float

```

round(-3.6)
- 4.0

```

Type: Float

The operation fractionPart computes the fractional part of x, that is, x - truncate x.

```

fractionPart 3.6
0.6

```

Type: Float

The operation digits allows the user to set the precision. It returns the previous value it was using.

```

digits 40
20

```

Type: PositiveInteger

```

sqrt 0.2
0.4472135954 9995793928 1834733746 2552470881

```

Type: Float

```
pi()$Float
3.1415926535 8979323846 2643383279 502884197
Type: Float
```

The precision is only limited by the computer memory available.
Calculations at 500 or more digits of precision are not difficult.

```
digits 500
40
Type: PositiveInteger
```

```
pi()$Float
3.1415926535 8979323846 2643383279 5028841971 6939937510 5820974944 592307816
4 0628620899 8628034825 3421170679 8214808651 3282306647 0938446095 505822317
2 5359408128 4811174502 8410270193 8521105559 6446229489 5493038196 442881097

3 0921861173 8193261179 3105118548 0744623799 6274956735 1885752724 891227938
1 830119491
Type: Float
```

Reset digits to its default value.

```
digits 20
500
Type: PositiveInteger
```

Numbers of type Float are represented as a record of two integers, namely, the mantissa and the exponent where the base of the exponent is binary. That is, the floating point number (m,e) represents the number $m \times 2^e$. A consequence of using a binary base is that decimal numbers can not, in general, be represented exactly.

```
=====
Output Functions
=====
```

A number of operations exist for specifying how numbers of type Float are to be displayed. By default, spaces are inserted every ten digits in the output for readability. Note that you cannot include spaces in the input form of a floating point number, though you can use underscores.

Output spacing can be modified with the outputSpacing operation. This inserts no spaces and then displays the value of x .

```
outputSpacing 0; x := sqrt 0.2
```

```
0.44721359549995793928
      Type: Float
```

Issue this to have the spaces inserted every 5 digits.

```
outputSpacing 5; x
0.44721 35954 99957 93928
      Type: Float
```

By default, the system displays floats in either fixed format or scientific format, depending on the magnitude of the number.

```
y := x/10**10
0.44721 35954 99957 93928 E -10
      Type: Float
```

A particular format may be requested with the operations `outputFloating` and `outputFixed`.

```
outputFloating(); x
0.44721 35954 99957 93928 E 0
      Type: Float
```

```
outputFixed(); y
0.00000 00000 44721 35954 99957 93928
      Type: Float
```

Additionally, you can ask for `n` digits to be displayed after the decimal point.

```
outputFloating 2; y
0.45 E -10
      Type: Float
```

```
outputFixed 2; x
0.45
      Type: Float
```

This resets the output printing to the default behavior.

```
outputGeneral()
      Type: Void
```

```
=====
An Example: Determinant of a Hilbert Matrix
=====
```

Consider the problem of computing the determinant of a 10 by 10 Hilbert matrix. The (i,j) -th entry of a Hilbert matrix is given by $1/(i+j+1)$.

First do the computation using rational numbers to obtain the exact result.

```
a: Matrix Fraction Integer:=matrix[ [1/(i+j+1) for j in 0..9] for i in 0..9]
+ 1 1 1 1 1 1 1 1 1 1+
|1 - - - - - - - - --|
| 2 3 4 5 6 7 8 9 10|
|
|1 1 1 1 1 1 1 1 1 1|
|- - - - - - - - -- --|
|2 3 4 5 6 7 8 9 10 11|
|
|1 1 1 1 1 1 1 1 1 1|
|- - - - - - - - -- -- --|
|3 4 5 6 7 8 9 10 11 12|
|
|1 1 1 1 1 1 1 1 1 1|
|- - - - - - - - -- -- --|
|4 5 6 7 8 9 10 11 12 13|
|
|1 1 1 1 1 1 1 1 1 1|
|- - - - - - - - -- -- --|
|5 6 7 8 9 10 11 12 13 14|
|
|1 1 1 1 1 1 1 1 1 1|
|- - - - - - - - -- -- --|
|6 7 8 9 10 11 12 13 14 15|
|
|1 1 1 1 1 1 1 1 1 1|
|- - - - - - - - -- -- --|
|7 8 9 10 11 12 13 14 15 16|
|
|1 1 1 1 1 1 1 1 1 1|
|- - - - - - - - -- -- --|
|8 9 10 11 12 13 14 15 16 17|
|
|1 1 1 1 1 1 1 1 1 1|
|- - - - - - - - -- -- --|
|9 10 11 12 13 14 15 16 17 18|
|
|1 1 1 1 1 1 1 1 1 1|
|- - - - - - - - -- -- --|
+10 11 12 13 14 15 16 17 18 19+
Type: Matrix Fraction Integer
```

This version of determinant uses Gaussian elimination.

```
d:= determinant a
```

```
-----
4620689394791469131629562883903627872698368000000000
Type: Fraction Integer
```

```
d :: Float
0.21641 79226 43149 18691 E -52
Type: Float
```

Now use hardware floats. Note that a semicolon (;) is used to prevent the display of the matrix.

```
b: Matrix DoubleFloat:=matrix[ [1/(i+j+1\DoubleFloat) for j in 0..9] for i in 0..9];
```

```
Type: Matrix DoubleFloat
```

The result given by hardware floats is correct only to four significant digits of precision. In the jargon of numerical analysis, the Hilbert matrix is said to be "ill-conditioned."

```
determinant b
2.1643677945721411E-53
Type: DoubleFloat
```

Now repeat the computation at a higher precision using Float.

```
digits 40
20
Type: PositiveInteger
```

```
c: Matrix Float := matrix [ [1/(i+j+1\Float) for j in 0..9] for i in 0..9];
Type: Matrix Float
```

```
determinant c
0.21641 79226 43149 18690 60594 98362 26174 36159 E -52
Type: Float
```

Reset digits to its default value.

```
digits 20
40
Type: PositiveInteger
```

— domain FLOAT Float —

```
)abbrev domain FLOAT Float
```

```
++ Author: Michael Monagan
++ Date Created: December 1987
++ Change History: 19 Jun 1990
++ Description:
++ \spadtype{Float} implements arbitrary precision floating point arithmetic.
++ The number of significant digits of each operation can be set
++ to an arbitrary value (the default is 20 decimal digits).
++ The operation \spad{float(mantissa,exponent,base)} for integer
++ \spad{mantissa}, \spad{exponent} specifies the number
++ \spad{mantissa * base ** exponent}
++ The underlying representation for floats is binary
++ not decimal. The implications of this are described below.
++
++ The model adopted is that arithmetic operations are rounded to
++ to nearest unit in the last place, that is, accurate to within
++ \spad{2**(-bits)}. Also, the elementary functions and constants are
++ accurate to one unit in the last place.
++ A float is represented as a record of two integers, the mantissa
++ and the exponent. The base of the representation is binary, hence
++ a \spad{Record(m:mantissa,e:exponent)} represents the number
++ \spad{m * 2 ** e}.
++ Though it is not assumed that the underlying integers are represented
++ with a binary base, the code will be most efficient when this is the
++ the case (this is true in most implementations of Lisp).
++ The decision to choose the base to be binary has some unfortunate
++ consequences. First, decimal numbers like 0.3 cannot be represented
++ exactly. Second, there is a further loss of accuracy during
++ conversion to decimal for output. To compensate for this, if d digits
++ of precision are specified, \spad{1 + ceiling(log2(10^d))} bits are used.
++ Two numbers that are displayed identically may therefore be
++ not equal. On the other hand, a significant efficiency loss would
++ be incurred if we chose to use a decimal base when the underlying
++ integer base is binary.
++
++ Algorithms used:
++ For the elementary functions, the general approach is to apply
++ identities so that the taylor series can be used, and, so
++ that it will converge within \spad{0( sqrt n )} steps. For example,
++ using the identity \spad{exp(x) = exp(x/2)**2}, we can compute
++ \spad{exp(1/3)} to n digits of precision as follows. We have
++ \spad{exp(1/3) = exp(2 ** (-sqrt s) / 3) ** (2 ** sqrt s)}.
++ The taylor series will converge in less than sqrt n steps and the
++ exponentiation requires sqrt n multiplications for a total of
++ \spad{2 sqrt n} multiplications. Assuming integer multiplication costs
++ \spad{0( n**2 )} the overall running time is \spad{0( sqrt(n) n**2 )}.
```

```

++ This approach is the best known approach for precisions up to
++ about 10,000 digits at which point the methods of Brent
++ which are \spad{0( log(n) n**2 )} become competitive. Note also that
++ summing the terms of the taylor series for the elementary
++ functions is done using integer operations. This avoids the
++ overhead of floating point operations and results in efficient
++ code at low precisions. This implementation makes no attempt
++ to reuse storage, relying on the underlying system to do
++ \spadgloss{garbage collection}. I estimate that the efficiency of this
++ package at low precisions could be improved by a factor of 2
++ if in-place operations were available.
++
++ Running times: in the following, n is the number of bits of precision\br
++ \spad{*}, \spad{ / }, \spad{sqrt}, \spad{pi}, \spad{exp1}, \spad{log2},
++ \spad{log10}: \spad{ 0( n**2 )} \br
++ \spad{exp}, \spad{log}, \spad{sin}, \spad{atan}: \spad{0(sqrt(n) n**2)}\br
++ The other elementary functions are coded in terms of the ones above.

B ==> Boolean

=====
Fraction examples
=====
```

The Fraction domain implements quotients. The elements must belong to a domain of category IntegralDomain: multiplication must be commutative and the product of two non-zero elements must not be zero. This allows you to make fractions of most things you would think of, but don't expect to create a fraction of two matrices! The abbreviation for Fraction is FRAC.

Use / to create a fraction.

```
a := 11/12
  11
  --
  12
                                Type: Fraction Integer
```

```
b := 23/24
  23
  --
  24
                                Type: Fraction Integer
```

The standard arithmetic operations are available.

```
3 - a*b**2 + a + b/a
313271
-----
76032
                                Type: Fraction Integer
```

Extract the numerator and denominator by using numer and denom, respectively.

```
numer(a)
  11
                                Type: PositiveInteger
```

```
denom(b)
  24
                                Type: PositiveInteger
```

Operations like max, min, negative?, positive? and zero? are all available if they are provided for the numerators and denominators.

Don't expect a useful answer from factor, gcd or lcm if you apply them to fractions.

```

r := (x**2 + 2*x + 1)/(x**2 - 2*x + 1)
      2
      x  + 2x + 1
      -----
      2
      x  - 2x + 1
Type: Fraction Polynomial Integer

```

Since all non-zero fractions are invertible, these operations have trivial definitions.

```

factor(r)
      2
      x  + 2x + 1
      -----
      2
      x  - 2x + 1
Type: Factored Fraction Polynomial Integer

```

Use `map` to apply `factor` to the numerator and denominator, which is probably what you mean.

```

map(factor,r)
      2
      (x + 1)
      -----
      2
      (x - 1)
Type: Fraction Factored Polynomial Integer

```

Other forms of fractions are available. Use `continuedFraction` to create a continued fraction.

```

continuedFraction(7/12)
      1 |      1 |      1 |      1 |
      +---+ + +---+ + +---+ + +---+
      | 1      | 1      | 2      | 2
Type: ContinuedFraction Integer

```

Use `partialFraction` to create a partial fraction.

```

partialFraction(7,12)
      3  1
      1 - -- + -
      2  3
      2
Type: PartialFraction Integer

```

Use `conversion` to create alternative views of fractions with objects

moved in and out of the numerator and denominator.

```
g := 2/3 + 4/5*i
      2   4
      - + - %i
      3   5
                                     Type: Complex Fraction Integer
```

```
g :: FRAC COMPLEX INT
      10 + 12%i
      -----
      15
                                     Type: Fraction Complex Integer
```

)abbrev domain FRAC Fraction
++ Author: Mark Botch
++ Date Last Updated: 12 February 1992
++ Basic Functions: Field, numer, denom
++ Description:
++ Fraction takes an IntegralDomain S and produces
++ the domain of Fractions with numerators and denominators from S.
++ If S is also a GcdDomain, then gcd's between numerator and
++ denominator will be cancelled during all operations.

Fraction(S: IntegralDomain): QuotientFieldCategory S with
  if S has IntegerNumberSystem and S has OpenMath then OpenMath
  if S has canonical and S has GcdDomain and S has canonicalUnitNormal
  then canonical
  ++ \spad{canonical} means that equal elements are in fact identical.
== LocalAlgebra(S, S, S) add

)abbrev domain FRIDEAL FractionalIdeal
++ Author: Manuel Bronstein
++ Date Created: 27 Jan 1989
++ Date Last Updated: 30 July 1993
++ Description:
++ Fractional ideals in a framed algebra.

FractionalIdeal(R, F, UP, A): Exports == Implementation where
  R : EuclideanDomain
  F : QuotientFieldCategory R
  UP: UnivariatePolynomialCategory F
  A : Join(FramedAlgebra(F, UP), RetractableTo F)

VF ==> Vector F
VA ==> Vector A
UPA ==> SparseUnivariatePolynomial A
QF ==> Fraction UP

Exports ==> Group with
  ideal   : VA -> %
    ++ ideal([f1,...,fn]) returns the ideal \spad{(f1,...,fn)}.
  basis   : % -> VA
    ++ basis((f1,...,fn)) returns the vector \spad{[f1,...,fn]}.
  norm    : % -> F
    ++ norm(I) returns the norm of the ideal I.
  numer   : % -> VA
    ++ numer(1/d * (f1,...,fn)) = the vector \spad{[f1,...,fn]}.
  denom   : % -> R
    ++ denom(1/d * (f1,...,fn)) returns d.
  minimize: % -> %
    ++ minimize(I) returns a reduced set of generators for \spad{I}.
  randomLC: (NonNegativeInteger, VA) -> A
    ++ randomLC(n,x) should be local but conditional.

Implementation ==> add

=====
FullPartialFractionExpansion expansion
=====

```

The domain FullPartialFractionExpansion implements factor-free conversion of quotients to full partial fractions.

Our examples will all involve quotients of univariate polynomials with rational number coefficients.

```

Fx := FRAC UP(x, FRAC INT)
      Fraction UnivariatePolynomial(x,Fraction Integer)
      Type: Domain

```

Here is a simple-looking rational function.

```

f : Fx := 36 / (x**5-2*x**4-2*x**3+4*x**2+x-2)
          36
-----
      5      4      3      2
      x  - 2x  - 2x  + 4x  + x - 2
          Type: Fraction UnivariatePolynomial(x,Fraction Integer)

```

We use fullPartialFraction to convert it to an object of type FullPartialFractionExpansion.

```

g := fullPartialFraction f
      4      4      --+      - 3%A - 6
      ---- - ---- + > -----
      x - 2   x + 1   --+      2
                      2      (x - %A)
                      %A  - 1= 0
Type: FullPartialFractionExpansion(Fraction Integer,
                                   UnivariatePolynomial(x,Fraction Integer))

```

Use a coercion to change it back into a quotient.

```
g :: Fx
      36
-----
      5      4      3      2
x  - 2x  - 2x  + 4x  + x  - 2
Type: Fraction UnivariatePolynomial(x,Fraction Integer)
```

Full partial fractions differentiate faster than rational functions.

```
g5 := D(g, 5)
      480      480      --+      2160%A + 4320
- ---- + ---- + > ----
      6      6      --+      7
(x - 2) (x + 1) 2 (x - %A)
      %A - 1 = 0
Type: FullPartialFractionExpansion(Fraction Integer,
UnivariatePolynomial(x,Fraction Integer))
```

```
f5 := D(f, 5)
      10      9      8      7      6
- 544320x  + 4354560x  - 14696640x  + 28615680x  - 40085280x
+
      5      4      3      2
46656000x  - 39411360x  + 18247680x  - 5870880x  + 3317760x + 246240
/
      20      19      18      17      16      15      14      13
x  - 12x  + 53x  - 76x  - 159x  + 676x  - 391x  - 1596x
+
      12      11      10      9      8      7      6      5
2527x  + 1148x  - 4977x  + 1372x  + 4907x  - 3444x  - 2381x  + 2924x
+
      4      3      2
276x  - 1184x  + 208x  + 192x - 64
Type: Fraction UnivariatePolynomial(x,Fraction Integer)
```

We can check that the two forms represent the same function.

```
g5::Fx - f5
0
Type: Fraction UnivariatePolynomial(x,Fraction Integer)
```

Here are some examples that are more complicated.

```
f : Fx := (x**5 * (x-1)) / ((x**2 + x + 1)**2 * (x-2)**3)
      6      5
x  - x
-----
      7      6      5      3      2
```

```

x  - 4x  + 3x  + 9x  - 6x  - 4x - 8
Type: Fraction UnivariatePolynomial(x,Fraction Integer)

g := fullPartialFraction f
      1952      464      32      179      135
      ----      ---      --      - ---- %A + ----

=====
MultivariatePolynomial
DistributedMultivariatePolynomial
HomogeneousDistributedMultivariatePolynomial
GeneralDistributedMultivariatePolynomial
=====

```

DistributedMultivariatePolynomial which is abbreviated as DMP and HomogeneousDistributedMultivariatePolynomial, which is abbreviated as HDMP, are very similar to MultivariatePolynomial except that they are represented and displayed in a non-recursive manner.

```
(d1,d2,d3) : DMP([z,y,x],FRAC INT)
              Type: Void
```

The constructor DMP orders its monomials lexicographically while HDMP orders them by total order refined by reverse lexicographic order.

```
d1 := -4*z + 4*y**2*x + 16*x**2 + 1
      2      2
      - 4z + 4y x + 16x + 1
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

d2 := 2*z*y**2 + 4*x + 1
      2
      2z y + 4x + 1
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

d3 := 2*z*x**2 - 2*y**2 - x
      2      2
      2z x - 2y - x
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)
```

These constructors are mostly used in Groebner basis calculations.

```
groebner [d1,d2,d3]
      1568 6 1264 5 6 4 182 3 2047 2 103 2857

      2      2      2      1      3
z  - 4y  + 2x  - - z - - x]
      4      2
Type: List HomogeneousDistributedMultivariatePolynomial([z,y,x],
Fraction Integer)

```

GeneralDistributedMultivariatePolynomial is somewhat more flexible in the sense that as well as accepting a list of variables to specify the variable ordering, it also takes a predicate on exponent vectors to specify the term ordering. With this polynomial type the user can experiment with the effect of using completely arbitrary term orderings. This flexibility is mostly important for algorithms such as Groebner basis calculations which can be very sensitive to term ordering.

— domain GDMP GeneralDistributedMultivariatePolynomial —

```

)abbrev domain GDMP GeneralDistributedMultivariatePolynomial
++ Author: Barry Trager
++ Description:
++ This type supports distributed multivariate polynomials
++ whose variables are from a user specified list of symbols.
++ The coefficient ring may be non commutative,
++ but the variables are assumed to commute.
++ The term ordering is specified by its third parameter.
++ Suggested types which define term orderings include:
++ \spadtype{DirectProduct}, \spadtype{HomogeneousDirectProduct},
++ \spadtype{SplitHomogeneousDirectProduct} and finally
++ \spadtype{OrderedDirectProduct} which accepts an arbitrary user
++ function to define a term ordering.

```

=====
GeneralSparseTable
=====

```

Sometimes when working with tables there is a natural value to use as the entry in all but a few cases. The GeneralSparseTable constructor can be used to provide any table type with a default value for entries.

Suppose we launched a fund-raising campaign to raise fifty thousand dollars. To record the contributions, we want a table with strings as keys (for the names) and integer entries (for the amount). In a data base of cash contributions, unless someone has been explicitly entered, it is reasonable to assume they have made a zero dollar contribution.

This creates a keyed access file with default entry 0.

```
patrons: GeneralSparseTable(String, Integer, KeyedAccessFile(Integer), 0) := table() ;
```

Now patrons can be used just as any other table. Here we record two gifts.

```
patrons."Smith" := 10500
```

```
patrons."Jones" := 22000
```

Now let us look up the size of the contributions from Jones and Stingy.

```
patrons."Jones"
```

```
patrons."Stingy"
```

Have we met our seventy thousand dollar goal?

```
reduce(+, entries patrons)
```

So the project is cancelled and we can delete the data base:

```
)system rm -r kaf*.sdata
```

=====

GeneralTriangularSet examples

=====

A domain constructor of the category TriangularSetCategory. The only requirement for a list of polynomials to be a member of such a domain is the following: no polynomial is constant and two distinct polynomials have distinct main variables. Such a triangular set may not be auto-reduced or consistent. Triangular sets are stored as sorted lists w.r.t. the main variables of their members but they are displayed in reverse order.

```
)abbrev domain GTSET GeneralTriangularSet
++ Author: Marc Moreno Maza (marc@nag.co.uk)
```

```

++ Date Created: 10/06/1995
++ Date Last Updated: 06/12/1996
++ References :
++ [1] P. AUBRY, D. LAZARD and M. MORENO MAZA "On the Theories
++      of Triangular Sets" Journal of Symbol. Comp. (to appear)
++ Description:
++ A domain constructor of the category \axiomType{TriangularSetCategory}.
++ The only requirement for a list of polynomials to be a member of such
++ a domain is the following: no polynomial is constant and two distinct
++ polynomials have distinct main variables. Such a triangular set may
++ not be auto-reduced or consistent. Triangular sets are stored
++ as sorted lists w.r.t. the main variables of their members but they
++ are displayed in reverse order.

GeneralUnivariatePowerSeries examples

=====

This is a category of univariate Puiseux series constructed from univariate Laurent series. A Puiseux series is represented by a pair $[r, f(x)]$, where r is a positive rational number and $f(x)$ is a Laurent series. This pair represents the Puiseux series $f(x^r)$.

graphImage : () -> $
++ graphImage() returns an empty graph with 0 point lists
++ of the domain \spadtype{GraphImage}. A graph image contains
++ the graph data component of a two dimensional viewport.
makeGraphImage : $ -> $
++ makeGraphImage(gi) takes the given graph, \spad{gi} of the
++ domain \spadtype{GraphImage}, and sends it's data to the
++ viewport manager where it waits to be included in a two-dimensional
++ viewport window. \spad{gi} cannot be an empty graph, and it's
++ elements must have been created using the \spadfun{point} or
++ \spadfun{component} functions, not by a previous
++ \spadfun{makeGraphImage}.
makeGraphImage : (L L P) -> $
++ makeGraphImage(llp) returns a graph of the domain
++ \spadtype{GraphImage} which is composed of the points and
++ lines from the list of lists of points, \spad{llp}, with
++ default point size and default point and line colours. The graph

```

```

++ data is then sent to the viewport manager where it waits to be
++ included in a two-dimensional viewport window.
makeGraphImage : (L L P,L PAL,L PAL,L PI) -> $
++ makeGraphImage(llp,lpal1,lpal2,lp) returns a graph of the
++ domain \spadtype{GraphImage} which is composed of the points
++ and lines from the list of lists of points, \spad{llp}, whose
++ point colors are indicated by the list of palette colors,
++ \spad{lpal1}, and whose lines are colored according to the list
++ of palette colors, \spad{lpal2}. The parameter lp is a list of
++ integers which denote the size of the data points. The graph
++ data is then sent to the viewport manager where it waits to be
++ included in a two-dimensional viewport window.
makeGraphImage : (L L P,L PAL,L PAL,L PI,L DROP) -> $
++ makeGraphImage(llp,lpal1,lpal2,lp,lopt) returns a graph of
++ the domain \spadtype{GraphImage} which is composed of the
++ points and lines from the list of lists of points, \spad{llp},
++ whose point colors are indicated by the list of palette colors,
++ \spad{lpal1}, and whose lines are colored according to the list
++ of palette colors, \spad{lpal2}. The parameter lp is a list of
++ integers which denote the size of the data points, and \spad{lopt}
++ is the list of draw command options. The graph data is then sent
++ to the viewport manager where it waits to be included in a
++ two-dimensional viewport window.
pointLists : $ -> L L P
++ pointLists(gi) returns the list of lists of points which compose
++ the given graph, \spad{gi}, of the domain \spadtype{GraphImage}.
key : $ -> I
++ key(gi) returns the process ID of the given graph, \spad{gi},
++ of the domain \spadtype{GraphImage}.
ranges : $ -> RANGEF
++ ranges(gi) returns the list of ranges of the point components from
++ the indicated graph, \spad{gi}, of the domain \spadtype{GraphImage}.
ranges : ($,RANGEF) -> RANGEF
++ ranges(gi,lr) modifies the list of ranges for the given graph,
++ \spad{gi} of the domain \spadtype{GraphImage}, to be that of the
++ list of range segments, \spad{lr}, and returns the new range list
++ for \spad{gi}.
units : $ -> UNITF
++ units(gi) returns the list of unit increments for the x and y
++ axes of the indicated graph, \spad{gi}, of the domain
++ \spadtype{GraphImage}.
units : ($,UNITF) -> UNITF
++ units(gi,lu) modifies the list of unit increments for the x and y
++ axes of the given graph, \spad{gi} of the domain
++ \spadtype{GraphImage}, to be that of the list of unit increments,
++ \spad{lu}, and returns the new list of units for \spad{gi}.
component : ($,L P,PAL,PAL,PI) -> Void
++ component(gi,lp,pal1,pal2,p) sets the components of the
++ graph, \spad{gi} of the domain \spadtype{GraphImage}, to the
++ values given. The point list for \spad{gi} is set to the list

```

```

++ \spad{lp}, the color of the points in \spad{lp} is set to
++ the palette color \spad{pal1}, the color of the lines which
++ connect the points \spad{lp} is set to the palette color
++ \spad{pal2}, and the size of the points in \spad{lp} is given
++ by the integer p.
component      : ($,P)                                -> Void
++ component(gi,pt) modifies the graph \spad{gi} of the domain
++ \spadtype{GraphImage} to contain one point component, \spad{pt}
++ whose point color, line color and point size are determined by
++ the default functions \spadfun{pointColorDefault},
++ \spadfun{lineColorDefault}, and \spadfun{pointSizeDefault}.
component      : ($,P,PAL,PAL,PI)                    -> Void
++ component(gi,pt,pal1,pal2,ps) modifies the graph \spad{gi} of
++ the domain \spadtype{GraphImage} to contain one point component,
++ \spad{pt} whose point color is set to the palette color \spad{pal1},
++ line color is set to the palette color \spad{pal2}, and point
++ size is set to the positive integer \spad{ps}.
appendPoint    : ($,P)                                -> Void
++ appendPoint(gi,pt) appends the point \spad{pt} to the end
++ of the list of points component for the graph, \spad{gi}, which is
++ of the domain \spadtype{GraphImage}.
point          : ($,P,PAL)                            -> Void
++ point(gi,pt,pal) modifies the graph \spad{gi} of the domain
++ \spadtype{GraphImage} to contain one point component, \spad{pt}
++ whose point color is set to be the palette color \spad{pal}, and
++ whose line color and point size are determined by the default
++ functions \spadfun{lineColorDefault} and \spadfun{pointSizeDefault}.
coerce         : L L P                                -> $
++ coerce(llp)
++ component(gi,pt) creates and returns a graph of the domain
++ \spadtype{GraphImage} which is composed of the list of list
++ of points given by \spad{llp}, and whose point colors, line colors
++ and point sizes are determined by the default functions
++ \spadfun{pointColorDefault}, \spadfun{lineColorDefault}, and
++ \spadfun{pointSizeDefault}. The graph data is then sent to the
++ viewport manager where it waits to be included in a two-dimensional
++ viewport window.
coerce         : $                                    -> E
++ coerce(gi) returns the indicated graph, \spad{gi}, of domain
++ \spadtype{GraphImage} as output of the domain \spadtype{OutputForm}.
putColorInfo   : (L L P,L PAL)                        -> L L P
++ putColorInfo(llp,lpal) takes a list of list of points, \spad{llp},
++ and returns the points with their hue and shade components
++ set according to the list of palette colors, \spad{lpal}.
figureUnits : L L P                                -> UNITSF

)abbrev domain GOPT GuessOption
++ Author: Martin Rubey
++ Description:
++ GuessOption is a domain whose elements are various options used
++ by Guess.
GuessOption(): Exports == Implementation where

Exports == SetCategory with
```

```

maxDerivative: Union(NonNegativeInteger, "arbitrary") -> %
++ maxDerivative(d) specifies the maximum derivative in an algebraic
++ differential equation. This option is expressed in the form
++ \spad{maxDerivative == d}.

maxShift: Union(NonNegativeInteger, "arbitrary") -> %
++ maxShift(d) specifies the maximum shift in a recurrence
++ equation. This option is expressed in the form \spad{maxShift == d}.

maxSubst: Union(PositiveInteger, "arbitrary") -> %
++ maxSubst(d) specifies the maximum degree of the monomial substituted
++ into the function we are looking for. That is, if \spad{maxSubst ==
++ d}, we look for polynomials such that  $\$p(f(x), f(x^2), \dots,$ 
++  $f(x^d))=0\$$ . equation. This option is expressed in the form
++ \spad{maxSubst == d}.

maxPower: Union(PositiveInteger, "arbitrary") -> %
++ maxPower(d) specifies the maximum degree in an algebraic differential
++ equation. For example, the degree of  $(f'')^3 f'$  is 4. maxPower(-1)
++ specifies that the maximum exponent can be arbitrary. This option is
++ expressed in the form \spad{maxPower == d}.

homogeneous: Union(PositiveInteger, Boolean) -> %
++ homogeneous(d) specifies whether we allow only homogeneous algebraic
++ differential equations. This option is expressed in the form
++ \spad{homogeneous == d}. If true, then maxPower must be
++ set, too, and ADEs with constant total degree are allowed.
++ If a PositiveInteger is given, only ADE's with this total degree are
++ allowed.

Somos: Union(PositiveInteger, Boolean) -> %
++ Somos(d) specifies whether we want that the total degree of the
++ differential operators is constant, and equal to d, or maxDerivative
++ if true. If true, maxDerivative must be set, too.

maxLevel: Union(NonNegativeInteger, "arbitrary") -> %
++ maxLevel(d) specifies the maximum number of recursion levels operators
++ guessProduct and guessSum will be applied. This option is expressed in
++ the form \spad{maxLevel == d}.

maxDegree: Union(NonNegativeInteger, "arbitrary") -> %
++ maxDegree(d) specifies the maximum degree of the coefficient
++ polynomials in an algebraic differential equation or a recursion with
++ polynomial coefficients. For rational functions with an exponential
++ term, \spad{maxDegree} bounds the degree of the denominator
++ polynomial.
++ This option is expressed in the form \spad{maxDegree == d}.

maxMixedDegree: NonNegativeInteger -> %

```

```

++ maxMixedDegree(d) specifies the maximum q-degree of the coefficient
++ polynomials in a recurrence with polynomial coefficients, in the case
++ of mixed shifts. Although slightly inconsistent, maxMixedDegree(0)
++ specifies that no mixed shifts are allowed. This option is expressed
++ in the form \spad{maxMixedDegree == d}.

allDegrees: Boolean -> %
++ allDegrees(d) specifies whether all possibilities of the degree vector
++ - taking into account maxDegree - should be tried. This is mainly
++ interesting for rational interpolation. This option is expressed in
++ the form \spad{allDegrees == d}.

safety: NonNegativeInteger -> %
++ safety(d) specifies the number of values reserved for testing any
++ solutions found. This option is expressed in the form \spad{safety ==
++ d}.

check: Union("skip", "MonteCarlo", "deterministic") -> %
++ check(d) specifies how we want to check the solution. If
++ the value is "skip", we return the solutions found by the
++ interpolation routine without checking. If the value is
++ "MonteCarlo", we use a probabilistic check. This option is
++ expressed in the form \spad{check == d}

checkExtraValues: Boolean -> %
++ checkExtraValues(d) specifies whether we want to check the
++ solution beyond the order given by the degree bounds. This
++ option is expressed in the form \spad{checkExtraValues == d}

one: Boolean -> %
++ one(d) specifies whether we are happy with one solution. This option
++ is expressed in the form \spad{one == d}.

debug: Boolean -> %
++ debug(d) specifies whether we want additional output on the
++ progress. This option is expressed in the form \spad{debug == d}.

functionName: Symbol -> %
++ functionName(d) specifies the name of the function given by the
++ algebraic differential equation or recurrence. This option is
++ expressed in the form \spad{functionName == d}.

functionNames: List(Symbol) -> %
++ functionNames(d) specifies the names for the function in
++ algebraic dependence. This option is
++ expressed in the form \spad{functionNames == d}.

variableName: Symbol -> %
++ variableName(d) specifies the variable used in by the algebraic
++ differential equation. This option is expressed in the form

```

```

++ \spad{variableName == d}.

indexName: Symbol -> %
++ indexName(d) specifies the index variable used for the formulas. This
++ option is expressed in the form \spad{indexName == d}.

displayKind: Symbol -> %
++ displayKind(d) specifies kind of the result: generating function,
++ recurrence or equation. This option should not be set by the
++ user, but rather by the HP-specification.

option : (List %, Symbol) -> Union(Any, "failed")
++ option(l, option) returns which options are given.

— domain GOPT0 GuessOptionFunctions0 —

```

)abbrev domain GOPT0 GuessOptionFunctions0
++ Author: Martin Rubey
++ Description:
++ GuessOptionFunctions0 provides operations that extract the
++ values of options for Guess.
GuessOptionFunctions0(): Exports == Implementation where

  LGOPT ==> List GuessOption

Exports == SetCategory with

  maxDerivative: LGOPT -> Union(NonNegativeInteger, "arbitrary")
    ++ maxDerivative returns the specified maxDerivative.

  maxShift: LGOPT -> Union(NonNegativeInteger, "arbitrary")
    ++ maxShift returns the specified maxShift.

  maxSubst: LGOPT -> Union(PositiveInteger, "arbitrary")
    ++ maxSubst returns the specified maxSubst.

  maxPower: LGOPT -> Union(PositiveInteger, "arbitrary")
    ++ maxPower returns the specified maxPower.

  homogeneous: LGOPT -> Union(PositiveInteger, Boolean)
    ++ homogeneous returns whether we allow only homogeneous algebraic
    ++ differential equations, default being false

```

```

Somos: LGOPT -> Union(PositiveInteger, Boolean)
  ++ Somos returns whether we allow only Somos-like operators, default
  ++ being false

maxLevel: LGOPT -> Union(NonNegativeInteger, "arbitrary")
  ++ maxLevel returns the specified maxLevel.

maxDegree: LGOPT -> Union(NonNegativeInteger, "arbitrary")
  ++ maxDegree returns the specified maxDegree.

maxMixedDegree: LGOPT -> NonNegativeInteger
  ++ maxMixedDegree returns the specified maxMixedDegree.

allDegrees: LGOPT -> Boolean
  ++ allDegrees returns whether all possibilities of the degree vector
  ++ should be tried, the default being false.

safety: LGOPT -> NonNegativeInteger
  ++ safety returns the specified safety or 1 as default.

check: LGOPT -> Union("skip", "MonteCarlo", "deterministic")
  ++ check(d) specifies how we want to check the solution. If
  ++ the value is "skip", we return the solutions found by the
  ++ interpolation routine without checking. If the value is
  ++ "MonteCarlo", we use a probabilistic check. The default is
  ++ "deterministic".

checkExtraValues: LGOPT -> Boolean
  ++ checkExtraValues(d) specifies whether we want to check the
  ++ solution beyond the order given by the degree bounds. The
  ++ default is true.

one: LGOPT -> Boolean
  ++ one returns whether we need only one solution, default being true.

functionName: LGOPT -> Symbol
  ++ functionName returns the name of the function given by the algebraic
  ++ differential equation, default being f

variableName: LGOPT -> Symbol
  ++ variableName returns the name of the variable used in by the
  ++ algebraic differential equation, default being x

indexName: LGOPT -> Symbol
  ++ indexName returns the name of the index variable used for the
  ++ formulas, default being n

displayAsGF: LGOPT -> Boolean
  ++ displayAsGF specifies whether the result is a generating function

```

```

++ or a recurrence. This option should not be set by the user, but rather
++ by the HP-specification, therefore, there is no default.

debug: LGOPT -> Boolean
++ debug returns whether we want additional output on the progress,
++ default being false

checkOptions: LGOPT -> Void
++ checkOptions checks whether the given options are consistent, and
++ yields an error otherwise

— Heap.help —

Heap examples

The domain Heap(S) implements a priority queue of objects of type S such that the operation extract! removes and returns the maximum element. The implementation represents heaps as flexible arrays. The representation and algorithms give complexity of $O(\log(n))$ for insertion and extractions, and $O(n)$ for construction.

Create a heap of five elements:

```
a:Heap INT:= heap [1,2,3,4,5]
               [5,4,2,1,3]
```

Use bag to convert a Bag into a Heap:

```
bag([1,2,3,4,5])$Heap(INT)
    [5,4,3,1,2]
```

The operation copy can be used to copy a Heap:

```
c:=copy a
    [5,4,2,1,3]
```

Use empty? to check if the heap is empty:

```
empty? a
    false
```

Use empty to create a new, empty heap:

```
b:=empty()$(Heap INT)
    []
```

and we can see that the newly created heap is empty:

```
empty? b
    true
```

The eq? function compares the reference of one heap to another:

```
eq?(a,c)
    false
```

The extract! function removes largest element of the heap:

```
extract! a
    5
```

Now extract! elements repeatedly until none are left, collecting the elements in a list.

```
[extract!(h) while not empty?(h)]
    [9,7,3,2,- 4,- 7]
                                Type: List Integer
```

Another way to produce the same result is by defining a heapsort function.

```
heapsort(x) == (empty? x => []; cons(extract!(x),heapsort x))
```

Type: Void

Create another sample heap.

```
h1 := heap [17,-4,9,-11,2,7,-7]
      [17,2,9,- 11,- 4,7,- 7]
      Type: Heap Integer
```

Apply heapsort to present elements in order.

```
heapsort h1
      [17,9,7,2,- 4,- 7,- 11]
      Type: List Integer
```

Heaps can be compared with =

```
(a=c)@Boolean
      false
```

and ~=

```
(a~=c)
      true
```

The inspect function shows the largest element in the heap:

```
inspect a
      4
```

The insert! function adds an element to the heap:

```
insert!(9,a)
      [9,4,2,1,3]
```

The map function applies a function to every element of the heap and returns a new heap:

```
map(x+>x+10,a)
      [19,14,12,11,13]
```

The original heap is unchanged:

```
a
      [9,4,2,1,3]
```

The map! function applies a function to every element of the heap and returns the original heap with modifications:

```
map!(x+>x+10,a)
      [19,14,12,11,13]
```

The original heap has been modified:

```
a
  [19,14,12,11,13]
```

The max function returns the largest element in the heap:

```
max a
  19
```

The merge function takes two heaps and creates a new heap with all of the elements:

```
merge(a,c)
  [19,14,12,11,13,5,4,2,1,3]
```

Notice that the original heap is unchanged:

```
a
  [19,14,12,11,13]
```

The merge! function takes two heaps and modifies the first heap argument to contain all of the elements:

```
merge!(a,c)
  [19,14,12,11,13,5,4,2,1,3]
```

Notice that the first argument was modified:

```
a
  [19,14,12,11,13,5,4,2,1,3]
```

but the second argument was not:

```
c
  [5,4,2,1,3]
```

A new, empty heap can be created with sample:

```
sample()$Heap(INT)
  []
```

The # function gives the size of the heap:

```
#a
  10
```

The any? function tests each element against a predicate function and returns true if any pass:

```
any?(x+-(x=14),a)
true
```

The `every?` function tests each element against a predicate function and returns true if they all pass:

```
every?(x+-(x=11),a)
false
```

The `parts` function returns a list of the elements in the heap:

```
parts a
[19,14,12,11,13,5,4,2,1,3]
```

The `size?` predicate compares the size of the heap to a value:

```
size?(a,9)
false
```

The `more?` predicate asks if the heap size is larger than a value:

```
more?(a,9)
true
```

The `less?` predicate asks if the heap size is smaller than a value:

```
less?(a,9)
false
```

The `members` function returns a list of the elements of the heap:

```
members a
[19,14,12,11,13,5,4,2,1,3]
```

The `member?` predicate asks if an element is in the heap:

```
member?(14,a)
true
```

The `count` function has two forms, one of which counts the number of copies of an element in the heap:

```
count(14,a)
1
```

The second form of the `count` function accepts a predicate to test against each member of the heap and counts the number of true results:

```
count(x+-(x>13),a)
```

— HexadecimalExpansion.help —

```
=====
HexadecimalExpansion
=====
```

All rationals have repeating hexadecimal expansions. The operation `hex` returns these expansions of type `HexadecimalExpansion`. Operations to access the individual numerals of a hexadecimal expansion can be obtained by converting the value to `RadixExpansion(16)`. More examples of expansions are available in the `DecimalExpansion`, `BinaryExpansion`, and `RadixExpansion`.

This is a hexadecimal expansion of a rational number.

```
r := hex(22/7)
    ---
    3.249
                                Type: HexadecimalExpansion
```

Arithmetic is exact.

```
r + hex(6/7)
    4
                                Type: HexadecimalExpansion
```

The period of the expansion can be short or long ...

```
[hex(1/i) for i in 350..354]
    -----
    [0.00BB3EE721A54D88, 0.00BAB6561, 0.00BA2E8, 0.00B9A7862A0FF465879D5F,
    0.00B92143FA36F5E02E4850FE8DBD78]
                                Type: List HexadecimalExpansion
```

or very long!

```
hex(1/1007)
    -----
    0.0041149783F0BF2C7D13933192AF6980619EE345E91EC2BB9D5CCA5C071E40926E54E8D
    -----
    DAE24196C0B2F8A0AAD60DBA57F5D4C8536262210C74F1
                                Type: HexadecimalExpansion
```

These numbers are bona fide algebraic objects.

```
p := hex(1/4)*x**2 + hex(2/3)*x + hex(4/9)
    2      -      ---
    0.4x  + 0.Ax + 0.71C
```

```

package HTMLFORM HTMLFormat

Here I have put some information about 'how to use' and 'the benefits of' this HTML formatter. Also some information for programmers if they want to extend this package.

If you want information about creating output formatters in general then, rather than duplicating content here I refer you to `mathml.spad.pamphlet` containing the `MathMLFormat` domain by Arthur C. Ralfs. This contains useful information for writers of output formatters.

Overview

This package allows users to cut and paste output from the Axiom command line to a HTML page. This output is enabled by typing:

```
)set output html on
```

After this the command line will output html (in addition to other formats that are enabled) and this html code can then be copied and pasted into a HTML document.

The HTML produced is well formed XML, that is, all tags have equivalent closing tags.

Why output to HTML?

In some ways HTMLFormat is a compromise between the standard text output and specialised formats like MathMLFormat. The potential quality is never going to be as good as output to a specialised maths renderer but on the other hand it is a lot better than the clunky fixed width font text output. The quality is not the only issue though, the direct output in any format is unlikely to be exactly what the user wants, so possibly more important than quality is the ability to edit the output.

HTMLFormat has advantages that the other output formats don't, for instance,

- It works with any browser without the need for plugins (as far as I know most computers should have the required fonts)
- Users can easily annotate and add comments using colour, bold, underline and so on.
- Annotations can easily be done with whatever html editor or text editor you are familiar with.
- Edits to the output will cause the width of columns and so on to be automatically adjusted, no need to try to insert spaces to get the superscripts to line up again!
- It is very easy to customise output so, for instance, we can fit a lot of information in a compact space on the page.

Using the formatter

We can cause the command line interpreter to output in html by typing the following:

```
)set output html on
```

After this the command line will output html (in addition to other formats that are enabled) and this html code can then be copied and pasted into an existing HTML document.

If you do not already have an html page to copy the output to then you can create one with a text editor and entering the following:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN"
"http://www.w3.org/TR/xhtml11/DTD/xhtml11.dtd">
<html xmlns="http://www.w3.org/1999/xhtml" >
```

```

<head>
  <title>Enter Your Title Here</title>
</head>
<body>
  Copy and paste the output from command line here.
</body>
</html>

```

Or using any program that will export to html such as OpenOffice.org writer.

Form of the output

HTMLFormat does not try to interpret syntax, for instance in an example like:
 (1) -> integral(x^x,x)
 it just takes what OutputForm provides and does not try to replace
 %A with the bound variable x.

Matrix Formatting

A big requirement for me is to fit big matrices on ordinary web pages.

At the moment the default output for a matrix is a grid, however it easy to modify this for a single matrix, or a whole page or whole site by using css (cascading style sheets). For instance we can get a more conventional looking matrix by adding the following style to the top of the page after the `<head>` tag:

```

<style type="text/css">
#matl {border-left-style:solid}
#matr {border-right-style:solid}
#matlt {border-left-style:solid;border-top-style:solid}
#matrt {border-right-style:solid;border-top-style:solid}
#matlb {border-left-style:solid;border-bottom-style:solid}
#matrb {border-right-style:solid;border-bottom-style:solid}
</style>

```

There are many other possibilities, for instance we can generate a matrix with bars either side to indicate a determinant. All we have to do is change the css for the site, page or individual element.

Programmers Guide

This package converts from OutputForm, which is a hierarchical tree structure, to html which uses tags arranged in a hierarchical tree structure. So the package converts from one tree (graph) structure to another.

This conversion is done in two stages using an intermediate Tree String structure. This Tree String structure represents HTML where:

- leafs represents unstructured text
- string in leafs contains the text
- non-leafs represents xml elements
- string in non-leafs represents xml attributes

This is created by traversing `OutputForm` while building up the Tree String structure.

The second stage is to convert the Tree Structure to text. All text output is done using:

```
sayTeX$Lisp
```

I have not produced and output to String as I don't know a way to append to a long string efficiently and I don't know how to insert carriage- returns into a String.

Future Developments

There would be some benefits in creating a `XMLFormat` category which would contain common elements for all xml formatted outputs such as `HTMLFormat`, `MathMLFormat`, `SVGFormat` and `X3DFormat`. However programming effort might be better spent creating a version of `OutputForm` which has better syntax information.

— HTMLFormat.input —

```
)set break resume
)sys rm -f HTMLFormat.output
)spool HTMLFormat.output
)set message test on
)set message auto off
)clear all

```

=====
MultivariatePolynomial
DistributedMultivariatePolynomial
HomogeneousDistributedMultivariatePolynomial
GeneralDistributedMultivariatePolynomial
=====

```

DistributedMultivariatePolynomial which is abbreviated as DMP and HomogeneousDistributedMultivariatePolynomial, which is abbreviated as HDMP, are very similar to MultivariatePolynomial except that they are represented and displayed in a non-recursive manner.

```

(d1,d2,d3) : DMP([z,y,x],FRAC INT)
Type: Void

```

The constructor DMP orders its monomials lexicographically while HDMP orders them by total order refined by reverse lexicographic

order.

```

d1 := -4*z + 4*y**2*x + 16*x**2 + 1
      2      2
    - 4z + 4y x + 16x  + 1
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

d2 := 2*z*y**2 + 4*x + 1
      2
    2z y  + 4x + 1
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

d3 := 2*z*x**2 - 2*y**2 - x
      2      2
    2z x  - 2y  - x
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

```

These constructors are mostly used in Groebner basis calculations.

```

groebner [d1,d2,d3]
      1568 6 1264 5 6 4 182 3 2047 2 103 2857

z  - 4y  + 2x  - - z - - x]
      4      2
Type: List HomogeneousDistributedMultivariatePolynomial([z,y,x],
Fraction Integer)

```

GeneralDistributedMultivariatePolynomial is somewhat more flexible in the sense that as well as accepting a list of variables to specify the variable ordering, it also takes a predicate on exponent vectors to specify the term ordering. With this polynomial type the user can experiment with the effect of using completely arbitrary term orderings. This flexibility is mostly important for algorithms such as Groebner basis calculations which can be very sensitive to term ordering.

=====
IndexedFlexibleArray examples
=====
```

A FlexibleArray is the notion of an array intended to allow for growth at the end only. Hence the following efficient operations

```
append(x,a) meaning append item x at the end of the array a
delete(a,n)} meaning delete the last item from the array a
```

Flexible arrays support the other operations inherited from ExtensibleLinearAggregate. However, these are not efficient.

Flexible arrays combine the $O(1)$ access time property of arrays with growing and shrinking at the end in $O(1)$ (average) time. This is done by using an ordinary array which may have zero or more empty slots at the end. When the array becomes full it is copied into a new larger (50% larger) array. Conversely, when the array becomes less than 1/2 full, it is copied into a smaller array. Flexible arrays provide for an efficient implementation of many data structures in particular heaps, stacks and sets.

IndexedList examples
=====

```

IndexedList is a basic implementation of the functions in ListAggregate, often using functions in the underlying LISP system. The second parameter to the constructor (mn) is the beginning index of the list. That is, if l is a list, then elt(l,mn) is the first value. This constructor is probably best viewed as the implementation of singly-linked lists that are addressable by index rather than as a mere wrapper for LISP lists.

=====
IndexedMatrix examples
=====

```

An `IndexedMatrix` is a matrix where the minimal row and column indices are parameters of the type. The domains `Row` and `Col` are both `IndexedVectors`.

The index of the 'first' row may be obtained by calling the function `minRowIndex`. The index of the 'first' column may be obtained by calling the function `minColIndex`. The index of the first element of a 'Row' is the same as the index of the first column in a matrix and vice versa.

domain IARRAY2 IndexedTwoDimensionalArray

An IndexedTwoDimensionalArray is a 2-dimensional array where the minimal row and column indices are parameters of the type. Rows and columns are returned as IndexedOneDimensionalArray's with minimal indices matching those of the IndexedTwoDimensionalArray. The index of the 'first' row may be obtained by calling the function 'minRowIndex'. The index of the 'first' column may be obtained by calling the function 'minColIndex'. The index of the first element of a 'Row' is the same as the index of the first column in an array and vice versa.

++ Author: Clifton J. Williamson
```

```

++ Date Created: 21 December 1989
++ Date Last Updated: 25 February 1989
++ Description:
++ Internal package for dense Taylor series.
++ This is an internal Taylor series type in which Taylor series
++ are represented by a \spadtype{Stream} of \spadtype{Ring} elements.
++ For univariate series, the \spad{Stream} elements are the Taylor
++ coefficients. For multivariate series, the \spad{n}th Stream element
++ is a form of degree n in the power series variables.

InnerTaylorSeries(Coef): Exports == Implementation where
  Coef : Ring
  I ==> Integer
  NNI ==> NonNegativeInteger
  ST ==> Stream Coef
  STT ==> StreamTaylorSeriesOperations Coef

Exports ==> Ring with
  coefficients: % -> Stream Coef
    ++\spad{coefficients(x)} returns a stream of ring elements.
    ++ When x is a univariate series, this is a stream of Taylor
    ++ coefficients. When x is a multivariate series, the
    ++ \spad{n}th element of the stream is a form of
    ++ degree n in the power series variables.
  series: Stream Coef -> %
    ++\spad{series(s)} creates a power series from a stream of
    ++ ring elements.
    ++ For univariate series types, the stream s should be a stream
    ++ of Taylor coefficients. For multivariate series types, the
    ++ stream s should be a stream of forms the \spad{n}th element
    ++ of which is a
    ++ form of degree n in the power series variables.
  pole?: % -> Boolean
    ++\spad{pole?(x)} tests if the series x has a pole.
    ++ Note: this is false when x is a Taylor series.
  order: % -> NNI
    ++\spad{order(x)} returns the order of a power series x,
    ++ i.e. the degree of the first non-zero term of the series.
  order: (% , NNI) -> NNI
    ++\spad{order(x,n)} returns the minimum of n and the order of x.
  "*" : (Coef, %) -> %
    ++\spad{c*x} returns the product of c and the series x.
  "*" : (% , Coef) -> %
    ++\spad{x*c} returns the product of c and the series x.
  "*" : (% , Integer) -> %
    ++\spad{x*i} returns the product of integer i and the series x.
  if Coef has IntegralDomain then IntegralDomain
    --++ An IntegralDomain provides 'exquo'

Integer examples

=====

Axiom provides many operations for manipulating arbitrary precision integers. In this section we will show some of those that come from Integer itself plus some that are implemented in other packages.

\subsection{Basic Functions}

The size of an integer in Axiom is only limited by the amount of computer storage you have available. The usual arithmetic operations are available.

```
2**(5678 - 4856 + 2 * 17)
4804810770435008147181540925125924391239526139871682263473855610088084200076_
308293086342527091412083743074572278211496076276922026433435687527334980249_
539302425425230458177649495442143929053063884787051467457680738771416988598_
15495632935288783334250628775936
Type: PositiveInteger
```

There are a number of ways of working with the sign of an integer. Let's use this x as an example.

```
x := -101
- 101
Type: Integer
```

First of all, there is the absolute value function.

```
abs(x)
101
Type: PositiveInteger
```

The sign operation returns -1 if its argument is negative, 0 if zero and 1 if positive.

```
sign(x)
- 1
Type: Integer
```

You can determine if an integer is negative in several other ways.

```
x < 0
true
Type: Boolean

x <= -1
true
Type: Boolean

negative?(x)
true
Type: Boolean
```

Similarly, you can find out if it is positive.

```
x > 0
false
Type: Boolean

x >= 1
false
Type: Boolean

positive?(x)
false
Type: Boolean
```

This is the recommended way of determining whether an integer is zero.

```
zero?(x)
false
Type: Boolean
```

Use the `zero?` operation whenever you are testing any mathematical object for equality with zero. This is usually more efficient than using `=` (think of matrices: it is easier to tell if a matrix is zero by just checking term by term than constructing another "zero" matrix and comparing the two matrices term by term) and also avoids the problem that `=` is usually used for creating equations.

This is the recommended way of determining whether an integer is equal to one.

```
one?(x)
false
Type: Boolean
```

This syntax is used to test equality using `=`. It says that you want a Boolean (true or false) answer rather than an equation.

```
(x = -101)@Boolean
```

```
true
```

```
Type: Boolean
```

The operations `odd?` and `even?` determine whether an integer is odd or even, respectively. They each return a Boolean object.

```
odd?(x)
```

```
true
```

```
Type: Boolean
```

```
even?(x)
```

```
false
```

```
Type: Boolean
```

The operation `gcd` computes the greatest common divisor of two integers.

```
gcd(56788,43688)
```

```
4
```

```
Type: PositiveInteger
```

The operation `lcm` computes their least common multiple.

```
lcm(56788,43688)
```

```
620238536
```

```
Type: PositiveInteger
```

To determine the maximum of two integers, use `max`.

```
max(678,567)
```

```
678
```

```
Type: PositiveInteger
```

To determine the minimum, use `min`.

```
min(678,567)
```

```
567
```

```
Type: PositiveInteger
```

The `reduce` operation is used to extend binary operations to more than two arguments. For example, you can use `reduce` to find the maximum integer in a list or compute the least common multiple of all integers in the list.

```
reduce(max,[2,45,-89,78,100,-45])
```

```
100
```

```
Type: PositiveInteger
```

```
reduce(min,[2,45,-89,78,100,-45])
```

```
- 89
```

```
Type: Integer
```

```
reduce(gcd,[2,45,-89,78,100,-45])
1
Type: PositiveInteger
```

```
reduce(lcm,[2,45,-89,78,100,-45])
1041300
Type: PositiveInteger
```

The infix operator "/" is not used to compute the quotient of integers. Rather, it is used to create rational numbers as described in Fraction.

```
13 / 4
13
--
4
Type: Fraction Integer
```

The infix operation quo computes the integer quotient.

```
13 quo 4
3
Type: PositiveInteger
```

The infix operation rem computes the integer remainder.

```
13 rem 4
1
Type: PositiveInteger
```

One integer is evenly divisible by another if the remainder is zero. The operation exquo can also be used.

```
zero?(167604736446952 rem 2003644)
true
Type: Boolean
```

The operation divide returns a record of the quotient and remainder and thus is more efficient when both are needed.

```
d := divide(13,4)
[quotient= 3,remainder= 1]
Type: Record(quotient: Integer,remainder: Integer)

d.quotient
3
Type: PositiveInteger
```

See help on Records for details on Records.

```
d.remainder
1
```

Type: PositiveInteger

```
=====
Primes and Factorization
=====
```

Use the operation factor to factor integers. It returns an object of type Factored Integer.

```
factor 102400
12 2
2 5
```

Type: Factored Integer

The operation prime? returns true or false depending on whether its argument is a prime.

```
prime? 7
true
```

Type: Boolean

```
prime? 8
false
```

Type: Boolean

The operation nextPrime returns the least prime number greater than its argument.

```
nextPrime 100
101
```

Type: PositiveInteger

The operation prevPrime returns the greatest prime number less than its argument.

```
prevPrime 100
97
```

Type: PositiveInteger

To compute all primes between two integers (inclusively), use the operation primes.

```
primes(100,175)
[173,167,163,157,151,149,139,137,131,127,113,109,107,103,101]
```

Type: List Integer

You might sometimes want to see the factorization of an integer when it is considered a Gaussian integer.

```

factor(2 :: Complex Integer)
      2
- %i (1 + %i)
      Type: Factored Complex Integer

```

=====

Some Number Theoretic Functions

=====

Axiom provides several number theoretic operations for integers.

The operation `fibonacci` computes the Fibonacci numbers. The algorithm has running time $O(\log^3 n)$ for argument n .

```

[fibonacci(k) for k in 0..]
[0,1,1,2,3,5,8,13,21,34,...]
      Type: Stream Integer

```

The operation `legendre` computes the Legendre symbol for its two integer arguments where the second one is prime. If you know the second argument to be prime, use `jacobi` instead where no check is made.

```

[legendre(i,11) for i in 0..10]
[0,1,- 1,1,1,1,- 1,- 1,- 1,1,- 1]
      Type: List Integer

```

The operation `jacobi` computes the Jacobi symbol for its two integer arguments. By convention, 0 is returned if the greatest common divisor of the numerator and denominator is not 1.

```

[jacobi(i,15) for i in 0..9]
[0,1,1,0,1,0,0,- 1,1,0]
      Type: List Integer

```

The operation `eulerPhi` computes the values of Euler's ϕ -function where $\phi(n)$ equals the number of positive integers less than or equal to n that are relatively prime to the positive integer n .

```

[eulerPhi i for i in 1..]
[1,1,2,2,4,2,6,4,6,4,...]
      Type: Stream Integer

```

The operation `moebiusMu` computes the Moebius μ function.

```

[moebiusMu i for i in 1..]
[1,- 1,- 1,0,- 1,1,- 1,0,0,1,...]
      Type: Stream Integer

```

IntegrationResult examples

=====

The result of a transcendental integration.

If a function f has an elementary integral g , then g can be written in the form

$$g = h + c_1 \log(u_1) + c_2 \log(u_2) + \dots + c_n \log(u_n)$$

where h , which is in the same field than f , is called the rational part of the integral, and

$$c_1 \log(u_1) + \dots + c_n \log(u_n)$$

is called the logarithmic part of the integral. This domain manipulates integrals represented in that form, by keeping both parts separately. The logs are not explicitly computed.

— Kernel.help —

=====

Kernel examples

=====

A kernel is a symbolic function application (such as $\sin(x+y)$) or a symbol (such as x). More precisely, a non-symbol kernel over a set S is an operator applied to a given list of arguments from S . The operator has type `BasicOperator` and the kernel object is usually part of an `Expression` object.

Kernels are created implicitly for you when you create expressions.

```
x :: Expression Integer
x
Type: Expression Integer
```

You can directly create a "symbol" kernel by using the kernel operation.

```
kernel x
x
Type: Kernel Expression Integer
```

This expression has two different kernels.

```
sin(x) + cos(x)
sin(x) + cos(x)
Type: Expression Integer
```

The operator kernels returns a list of the kernels in an object of type Expression.

```
kernels %
[sin(x),cos(x)]
Type: List Kernel Expression Integer
```

This expression also has two different kernels.

```
sin(x)**2 + sin(x) + cos(x)
2
sin(x) + sin(x) + cos(x)
Type: Expression Integer
```

The sin(x) kernel is used twice.

```
kernels %
[sin(x),cos(x)]
Type: List Kernel Expression Integer
```

An expression need not contain any kernels.

```
kernels(1 :: Expression Integer)
[]
Type: List Kernel Expression Integer
```

If one or more kernels are present, one of them is designated the main kernel.

```
mainKernel(cos(x) + tan(x))
tan(x)
Type: Union(Kernel Expression Integer,...)
```

Kernels can be nested. Use `height` to determine the nesting depth.

```
height kernel x
1
Type: PositiveInteger
```

This has height 2 because the `x` has height 1 and then we apply an operator to that.

```
height mainKernel(sin x)
2
Type: PositiveInteger
```

```
height mainKernel(sin cos x)
3
Type: PositiveInteger
```

```
height mainKernel(sin cos (tan x + sin x))
4
Type: PositiveInteger
```

Use the `operator` operation to extract the operator component of the kernel. The operator has type `BasicOperator`.

```
operator mainKernel(sin cos (tan x + sin x))
sin
Type: BasicOperator
```

Use the `name` operation to extract the name of the operator component of the kernel. The name has type `Symbol`. This is really just a shortcut for a two-step process of extracting the operator and then calling `name` on the operator.

```
name mainKernel(sin cos (tan x + sin x))
sin
Type: Symbol
```

Axiom knows about functions such as `sin`, `cos` and so on and can make kernels and then expressions using them. To create a kernel and expression using an arbitrary operator, use `operator`.

Now `f` can be used to create symbolic function applications.

```
f := operator 'f
f
Type: BasicOperator

e := f(x, y, 10)
f(x,y,10)
Type: Expression Integer
```

Use the `is?` operation to learn if the operator component of a kernel is equal to a given operator.

```
is?(e, f)
true
```

Type: Boolean

You can also use a symbol or a string as the second argument to `is?`.

```
is?(e, 'f')
true
```

Type: Boolean

Use the `argument` operation to get a list containing the argument component of a kernel.

```
argument mainKernel e
[x,y,10]
```

Type: List Expression Integer

Conceptually, an object of type `Expression` can be thought of a quotient of multivariate polynomials, where the "variables" are kernels. The arguments of the kernels are again expressions and so the structure recurses. See `Expression` for examples of using kernels to take apart expression objects.
