=====

KeyedAccessFile examples

=====

The domain KeyedAccessFile(S) provides files which can be used as associative tables. Data values are stored in these files and can be retrieved according to their keys. The keys must be strings so this type behaves very much like the StringTable(S) domain. The difference is that keyed access files reside in secondary storage while string tables are kept in memory.

Before a keyed access file can be used, it must first be opened. A new file can be created by opening it for output.

```
ey: KeyedAccessFile(Integer) := open("editor.year", "output")
```

Just as for vectors, tables or lists, values are saved in a keyed access file by setting elements.

```
ey."Char" := 1986
```

```
ey."Caviness" := 1985
```

```
ey."Fitch" := 1984
```

Values are retrieved using application, in any of its syntactic forms.

```
ey."Char"
```

```
ey("Char")
```

```
ey "Char"
```

Attempting to retrieve a non-existent element in this way causes an error. If it is not known whether a key exists, you should use the

search operation.

```
search("Char", ey)

search("Smith", ey)
```

When an entry is no longer needed, it can be removed from the file.

```
remove!("Char", ey)
```

The keys operation returns a list of all the keys for a given file.

```
keys ey
```

The # operation gives the number of entries.

```
#ey
```

The table view of keyed access files provides safe operations. That is, if the Axiom program is terminated between file operations, the file is left in a consistent, current state. This means, however, that the operations are somewhat costly. For example, after each update the file is closed.

Here we add several more items to the file, then check its contents.

```
KE := Record(key: String, entry: Integer)

reopen!(ey, "output")
```

If many items are to be added to a file at the same time, then it is more efficient to use the write operation.

```
write!(ey, ["van Hulzen", 1983]$KE)

write!(ey, ["Calmet", 1982]$KE)

write!(ey, ["Wang", 1981]$KE)

close! ey
```

The read operation is also available from the file view, but it returns elements in a random order. It is generally clearer and more efficient to use the keys operation and to extract elements by key.

```
keys ey

members ey

)system rm -r editor.year
```

— domain KAFfile KeyedAccessFile —

```

)abbrev domain KAFfile KeyedAccessFile
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain allows a random access file to be viewed both as a table
++ and as a file object. The KeyedAccessFile format is a directory
++ containing a single file called "index.kaf". This file is a random
++ access file. The first thing in the file is an integer which is the
++ byte offset of an association list (the dictionary) at the end of
++ the file. The association list is of the form
++ ((key . byteoffset) (key . byteoffset)...)
++ where the byte offset is the number of bytes from the beginning of
++ the file. This offset contains an s-expression for the value of the key.

KeyedAccessFile(Entry): KAFcategory == KAFcapsule where
  Name ==> FileName
  Key ==> String
  Entry : SetCategory

KAFcategory ==
  Join(FileCategory(Name, Record(key: Key, entry: Entry)),
    TableAggregate(Key, Entry)) with
    finiteAggregate
    pack_!: % -> %
    ++ pack!(f) reorganizes the file f on disk to recover
    ++ unused space.

KAFcapsule == add

```
=====
Library examples
=====
```

The Library domain provides a simple way to store Axiom values in a file. This domain is similar to KeyedAccessFile but fewer declarations are needed and items of different types can be saved together in the same file.

To create a library, you supply a file name.

```
stuff := library "Neat.stuff"
```

Now values can be saved by key in the file. The keys should be mnemonic, just as the field names are for records. They can be given either as strings or symbols.

```
stuff.int := 32**2

stuff."poly" := x**2 + 1

stuff.str := "Hello"
```

You obtain the set of available keys using the keys operation.

```
keys stuff
```

You extract values by giving the desired key in this way.

```
stuff.poly
```

```
stuff("poly")
```

When the file is no longer needed, you should remove it from the file system.

```
)system rm -rf Neat.stuff
```

)abbrev domain LIB Library
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides a simple way to save values in files.

Library(): TableAggregate(String, Any) with
  library: FileName -> %
    ++ library(ln) creates a new library file.
  pack_!: % -> %
    ++ pack!(f) reorganizes the file f on disk to recover
    ++ unused space.

  elt : (% , Symbol) -> Any
    ++ elt(lib,k) or lib.k extracts the value corresponding to
    ++ the key \spad{k} from the library \spad{lib}.

  setelt : (% , Symbol, Any) -> Any
    ++ \spad{lib.k := v} saves the value \spad{v} in the library
    ++ \spad{lib}. It can later be extracted using the key \spad{k}.

  close_!: % -> %
    ++ close!(f) returns the library f closed to input and output.

== KeyedAccessFile(Any) add
  Rep := KeyedAccessFile(Any)
  library f == open f
  elt(f:%,v:Symbol) == elt(f, string v)
  setelt(f:%, v:Symbol, val:Any) == setelt(f, string v, val)

===== LieExponentials examples =====

Management of the Lie Group associated with a free nilpotent Lie algebra. Every Lie bracket with length greater than Order are assumed to be null. The implementation inherits from the XPBWPolynomial domain constructor: Lyndon coordinates are exponential coordinates of the second kind.

```
a: Symbol := 'a
a
Type: Symbol
```

```
b: Symbol := 'b
b
Type: Symbol
```

===== Declarations of domains =====

```
coef := Fraction(Integer)
Fraction Integer
Type: Domain

group := LieExponentials(Symbol, coef, 3)
LieExponentials(Symbol, Fraction Integer, 3)
Type: Domain

lpoly := LiePolynomial(Symbol, coef)
LiePolynomial(Symbol, Fraction Integer)
Type: Domain

poly := XPBWPolynomial(Symbol, coef)
XPBWPolynomial(Symbol, Fraction Integer)
Type: Domain
```

===== Calculations =====

```
ea := exp(a::lpoly)$group
[a]
e
Type: LieExponentials(Symbol, Fraction Integer, 3)
```

```

eb := exp(b::lpoly)$group

LieSquareMatrix examples

=====

LieSquareMatrix(n,R) implements the Lie algebra of the n by n matrices over the commutative ring R.

The Lie bracket (commutator) of the algebra is given by

$$a*b := (a * \$\$MATRIX(n,R) b - b * \$\$MATRIX(n,R) a)$$

where $\$\$MATRIX(n,R)$ is the usual matrix multiplication.

=====
LinearOrdinaryDifferentialOperator examples
=====

```

LinearOrdinaryDifferentialOperator(A, diff) is the domain of linear ordinary differential operators with coefficients in a ring A with a given derivation.

```
=====
Differential Operators with Series Coefficients
=====
```

Problem:

Find the first few coefficients of $\exp(x)/x^i$ of Dop phi where

```
Dop := D^3 + G/x^2 * D + H/x^3 - 1
phi := sum(s[i]*exp(x)/x^i, i = 0..)
```

Solution:

Define the differential.

```
Dx: LODO(EXPR INT, f +-> D(f, x))
      Type: Void

Dx := D()
D
Type: LinearOrdinaryDifferentialOperator(Expression Integer,
theMap LAMBDA-CLOSURE(NIL,NIL,NIL,G1404 envArg,
SPADCALL(G1404,QUOTE x,
ELT(*1;anonymousFunction;0;frame0;internal;MV,0))))
```

Now define the differential operator Dop.

```
Dop:= Dx^3 + G/x^2*Dx + H/x^3 - 1
      3
      G      - x  + H
D  + -- D + -----
      2          3
      x          x
Type: LinearOrdinaryDifferentialOperator(Expression Integer,
theMap LAMBDA-CLOSURE(NIL,NIL,NIL,G1404 envArg,
SPADCALL(G1404,QUOTE x,
ELT(*1;anonymousFunction;0;frame0;internal;MV,0))))
```

=====
LinearOrdinaryDifferentialOperator1 example
=====

```

LinearOrdinaryDifferentialOperator1(A) is the domain of linear ordinary differential operators with coefficients in the differential ring A.

```
=====
Differential Operators with Rational Function Coefficients
=====
```

This example shows differential operators with rational function coefficients. In this case operator multiplication is non-commutative and, since the coefficients form a field, an operator division algorithm exists.

We begin by defining RFZ to be the rational functions in x with integer coefficients and Dx to be the differential operator for d/dx.

```
RFZ := Fraction UnivariatePolynomial('x, Integer)
      Fraction UnivariatePolynomial(x,Integer)
      Type: Domain

x : RFZ := 'x
  x
                                     Type: Fraction UnivariatePolynomial(x,Integer)

Dx : LODO1 RFZ := D()
  D
                                     Type: LinearOrdinaryDifferentialOperator1
                                     Fraction UnivariatePolynomial(x,Integer)
```

Operators are created using the usual arithmetic operations.

```
b : LODO1 RFZ := 3*x**2*Dx**2 + 2*Dx + 1/x
      2 2      1
      3x D  + 2D + -
                        x
                                     Type: LinearOrdinaryDifferentialOperator1
                                     Fraction UnivariatePolynomial(x,Integer)

a : LODO1 RFZ := b*(5*x*Dx + 7)
      3 3      2      2      7
      15x D  + (51x  + 10x)D  + 29D + -
                        x
                                     Type: LinearOrdinaryDifferentialOperator1
                                     Fraction UnivariatePolynomial(x,Integer)
```

Operator multiplication corresponds to functional composition.

```
p := x**2 + 1/x**2
      4
      x  + 1
      ----
      2
      x
                                     Type: Fraction UnivariatePolynomial(x,Integer)
```

Since operator coefficients depend on x , the multiplication is not commutative.

$$\frac{(a*b - b*a) p}{x^4 - 75x^3 + 540x^2 - 75x}$$

Type: Fraction UnivariatePolynomial(x,Integer)

When the coefficients of operator polynomials come from a field, as in this case, it is possible to define operator division. Division on the left and division on the right yield different results when the multiplication is non-commutative.

The results of `leftDivide` and `rightDivide` are quotient-remainder pairs satisfying:

$$\begin{aligned} \text{leftDivide}(a,b) &= [q, r] \text{ such that } a = b*q + r \\ \text{rightDivide}(a,b) &= [q, r] \text{ such that } a = q*b + r \end{aligned}$$

In both cases, the degree of the remainder, r , is less than the degree of b .

```
ld := leftDivide(a,b)
[quotient= 5x D + 7,remainder= 0]
Type: Record(quotient: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer),
             remainder: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer))

a = b * ld.quotient + ld.remainder
3 3      2      2      7      3 3      2      2      7
15x D + (51x + 10x)D + 29D + -= 15x D + (51x + 10x)D + 29D + -
Type: Equation LinearOrdinaryDifferentialOperator1
Fraction UnivariatePolynomial(x,Integer)
```

The operations of left and right division are so-called because the quotient is obtained by dividing a on that side by b .

```
rd := rightDivide(a,b)
[quotient= 5x D + 7,remainder= 10D + -]
Type: Record(quotient: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer),
             remainder: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer))

a = rd.quotient * b + rd.remainder
3 3      2      2      7      3 3      2      2      7
```

```

15x D + (51x + 10x)D + 29D + -= 15x D + (51x + 10x)D + 29D + -
Type: Equation LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

Operations `rightQuotient` and `rightRemainder` are available if only one of the quotient or remainder are of interest to you. This is the quotient from right division.

```

rightQuotient(a,b)
5x D + 7
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

This is the remainder from right division. The corresponding "left" functions, `leftQuotient` and `leftRemainder` are also available.

```

rightRemainder(a,b)
5
10D + -
x
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

For exact division, operations `leftExactQuotient` and `rightExactQuotient` are supplied. These return the quotient but only if the remainder is zero. The call `rightExactQuotient(a,b)` would yield an error.

```

leftExactQuotient(a,b)
5x D + 7
Type: Union(LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer),...)

```

The division operations allow the computation of left and right greatest common divisors, `leftGcd` and `rightGcd` via remainder sequences, and consequently the computation of left and right least common multiples, `rightLcm` and `leftLcm`.

```

e := leftGcd(a,b)
2 2      1
3x D + 2D + -
x
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

Note that a greatest common divisor doesn't necessarily divide `a` and `b` on both sides. Here the left greatest common divisor does not divide `a` on the right.

```

leftRemainder(a, e)
0

```

```

Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

```

rightRemainder(a, e)
      5
10D + -
      x
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

Similarly, a least common multiple is not necessarily divisible from both sides.

```

f := rightLcm(a,b)
      3 3      2      2      7
15x D + (51x + 10x)D + 29D + -
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

```

rightRemainder(f, b)
      5
10D + -
      x
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

```

leftRemainder(f, b)
0
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

LinearOrdinaryDifferentialOperator2

`LinearOrdinaryDifferentialOperator2(A, M)` is the domain of linear ordinary differential operators with coefficients in the differential ring A and operating on M , an A -module. This includes the cases of operators which are polynomials in D acting upon scalar or vector expressions of a single variable. The coefficients of the operator polynomials can be integers, rational functions, matrices or elements of other domains.

```
=====
Differential Operators with Constant Coefficients
=====
```

This example shows differential operators with rational number coefficients operating on univariate polynomials.

We begin by making type assignments so we can conveniently refer to univariate polynomials in x over the rationals.

```
Q := Fraction Integer
Fraction Integer
                                Type: Domain

PQ := UnivariatePolynomial('x, Q)
UnivariatePolynomial(x,Fraction Integer)
                                Type: Domain

x: PQ := 'x
x
                                Type: UnivariatePolynomial(x,Fraction Integer)
```

Now we assign Dx to be the differential operator D corresponding to d/dx .

```
Dx: LOD02(Q, PQ) := D()
D
Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
UnivariatePolynomial(x,Fraction Integer))
```

New operators are created as polynomials in $D()$.

```
a := Dx + 1
D + 1
Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
UnivariatePolynomial(x,Fraction Integer))

b := a + 1/2*Dx**2 - 1/2
1 2      1
- D + D + -
2      2
Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
UnivariatePolynomial(x,Fraction Integer))
```

To apply the operator a to the value p the usual function call syntax is used.

```
p := 4*x**2 + 2/3
      2      2
      4x  + -
          3
Type: UnivariatePolynomial(x,Fraction Integer)
```

```
a p
      2      2
      4x  + 8x + -
          3
Type: UnivariatePolynomial(x,Fraction Integer)
```

Operator multiplication is defined by the identity $(a*b)p = a(b(p))$

```
(a * b) p = a b p
      2      37      2      37
      2x  + 12x + --- 2x  + 12x + ---
          3          3
Type: Equation UnivariatePolynomial(x,Fraction Integer)
```

Exponentiation follows from multiplication.

```
c := (1/9)*b*(a + b)^2
      1  6      5  5      13  4      19  3      79  2      7      1
      -- D  + -- D  + -- D  + -- D  + -- D  + -- D  + -
      72      36      24      18      72      12      8
Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
UnivariatePolynomial(x,Fraction Integer))
```

Finally, note that operator expressions may be applied directly.

```
(a**2 - 3/4*b + c) (p + 1)
      2      44      541
      3x  + -- x + ---
          3      36
Type: UnivariatePolynomial(x,Fraction Integer)
```

```
=====
Differential Operators with Matrix Coefficients Operating on Vectors}
=====
```

This is another example of linear ordinary differential operators with non-commutative multiplication. Unlike the rational function case, the differential ring of square matrices (of a given dimension) with univariate polynomial entries does not form a field. Thus the number of operations available is more limited.

In this section, the operators have three by three matrix coefficients with polynomial entries.

```
PZ := UnivariatePolynomial(x,Integer)
      UnivariatePolynomial(x,Integer)
      Type: Domain

x:PZ := 'x
      x
      Type: UnivariatePolynomial(x,Integer)

Mat := SquareMatrix(3,PZ)
      SquareMatrix(3,UnivariatePolynomial(x,Integer))
      Type: Domain
```

The operators act on the vectors considered as a Mat-module.

```
Vect := DPMM(3, PZ, Mat, PZ)
DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),SquareMatrix(3,UnivariatePolynomial(x,Integer)),UnivariatePolynomial(x,Integer))
      Type: Domain

Modo := LODD2(Mat, Vect)
LinearOrdinaryDifferentialOperator2(SquareMatrix(3,UnivariatePolynomial(x,Integer)),DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),SquareMatrix(3,UnivariatePolynomial(x,Integer)),UnivariatePolynomial(x,Integer)))
      Type: Domain
```

The matrix m is used as a coefficient and the vectors p and q are operated upon.

```
m:Mat := matrix [ [x^2,1,0],[1,x^4,0],[0,0,4*x^2] ]
      + 2      +
      |x  1  0 |
      |      |
      |  4  |
      |1  x  0 |
      |      |
      |      2|
      +0  0  4x +
      Type: SquareMatrix(3,UnivariatePolynomial(x,Integer))

p:Vect := directProduct [3*x^2+1,2*x,7*x^3+2*x]
      2      3
      [3x  + 1,2x,7x  + 2x]
      Type: DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
      SquareMatrix(3,UnivariatePolynomial(x,Integer)),
      UnivariatePolynomial(x,Integer))
```

```

q: Vect := m * p
      4      2      5      2      5      3
      [3x  + x  + 2x, 2x  + 3x  + 1, 28x  + 8x ]
      Type: DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
      SquareMatrix(3,UnivariatePolynomial(x,Integer)),
      UnivariatePolynomial(x,Integer))

```

Now form a few operators.

```

Dx : Mod0 := D()
D
      Type: LinearOrdinaryDifferentialOperator2(
      SquareMatrix(3,UnivariatePolynomial(x,Integer)),
      DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
      SquareMatrix(3,UnivariatePolynomial(x,Integer)),
      UnivariatePolynomial(x,Integer)))

```

```

a : Mod0 := Dx + m
      + 2      +
      |x  1    0 |
      |      |
      D + |      4 |
      |1   x   0 |
      |      |
      |      2|
      +0  0  4x +
      Type: LinearOrdinaryDifferentialOperator2(
      SquareMatrix(3,UnivariatePolynomial(x,Integer)),
      DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
      SquareMatrix(3,UnivariatePolynomial(x,Integer)),
      UnivariatePolynomial(x,Integer)))

```

```

b : Mod0 := m*Dx + 1
      + 2      +
      |x  1    0 |      +1  0  0+
      |      |      |      | |
      |      4 |      |D + |0  1  0|
      |1   x   0 |      |      |
      |      |      +0  0  1+
      |      2|
      +0  0  4x +
      Type: LinearOrdinaryDifferentialOperator2(
      SquareMatrix(3,UnivariatePolynomial(x,Integer)),
      DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
      SquareMatrix(3,UnivariatePolynomial(x,Integer)),
      UnivariatePolynomial(x,Integer)))

```

```

c := a*b
      + 2      +      + 4      4      2      +      + 2      +
      |x  1    0 |      |x  + 2x + 2      x  + x      0      |      |x  1    0 |

```

=====
List examples
=====

```

A list is a finite collection of elements in a specified order that can contain duplicates. A list is a convenient structure to work with because it is easy to add or remove elements and the length need not be constant. There are many different kinds of lists in Axiom, but the default types (and those used most often) are created by the List constructor. For example, there are objects of type List Integer, List Float and List Polynomial Fraction Integer. Indeed, you can even have List List List Boolean (that is, lists of lists of lists of Boolean values). You can have lists of any type of Axiom object.

```

=====
Creating Lists
=====

```

The easiest way to create a list with, for example, the elements 2, 4, 5, 6 is to enclose the elements with square brackets and separate the elements with commas.

The spaces after the commas are optional, but they do improve the readability.

```

[2, 4, 5, 6]
[2,4,5,6]

```

Type: List PositiveInteger

To create a list with the single element 1, you can use either [1] or the operation list.

```

[1]
list 1

```

Type: List PositiveInteger

```
list(1)
[1]
```

Type: List PositiveInteger

Once created, two lists *k* and *m* can be concatenated by issuing `append(k,m)`. `append` does not physically join the lists, but rather produces a new list with the elements coming from the two arguments.

```
append([1,2,3],[5,6,7])
[1,2,3,5,6,7]
```

Type: List PositiveInteger

Use `cons` to append an element onto the front of a list.

```
cons(10,[9,8,7])
[10,9,8,7]
```

Type: List PositiveInteger

=====

Accessing List Elements

=====

To determine whether a list has any elements, use the operation `empty?`.

```
empty? [x+1]
false
```

Type: Boolean

Alternatively, equality with the list constant `nil` can be tested.

```
([] = nil)@Boolean
true
```

Type: Boolean

We'll use this in some of the following examples.

```
k := [4,3,7,3,8,5,9,2]
[4,3,7,3,8,5,9,2]
```

Type: List PositiveInteger

Each of the next four expressions extracts the first element of *k*.

```
first k
4
```

Type: PositiveInteger

```
k.first
4
```

Type: PositiveInteger

```
k.1
  4
                                Type: PositiveInteger
```

```
k(1)
  4
                                Type: PositiveInteger
```

The last two forms generalize to `k.i` and `k(i)`, respectively, where $1 \leq i \leq n$ and n equals the length of `k`.

This length is calculated by `#`.

```
n := #k
  8
                                Type: PositiveInteger
```

Performing an operation such as `k.i` is sometimes referred to as indexing into `k` or elting into `k`. The latter phrase comes about because the name of the operation that extracts elements is called `elt`. That is, `k.3` is just alternative syntax for `elt(k,3)`. It is important to remember that list indices begin with 1. If we issue `k := [1,3,2,9,5]` then `k.4` returns 9. It is an error to use an index that is not in the range from 1 to the length of the list.

The last element of a list is extracted by any of the following three expressions.

```
last k
  2
                                Type: PositiveInteger
```

```
k.last
  2
                                Type: PositiveInteger
```

This form computes the index of the last element and then extracts the element from the list.

```
k.(#k)
  2
                                Type: PositiveInteger
```

```
=====
Changing List Elements
=====
```

We'll use this in some of the following examples.

```
k := [4,3,7,3,8,5,9,2]
      [4,3,7,3,8,5,9,2]
```

Type: List PositiveInteger

List elements are reset by using the `k.i` form on the left-hand side of an assignment. This expression resets the first element of `k` to 999.

```
k.1 := 999
      999
```

Type: PositiveInteger

As with indexing into a list, it is an error to use an index that is not within the proper bounds. Here you see that `k` was modified.

```
k
      [999,3,7,3,8,5,9,2]
```

Type: List PositiveInteger

The operation that performs the assignment of an element to a particular position in a list is called `setelt`. This operation is destructive in that it changes the list. In the above example, the assignment returned the value 999 and `k` was modified. For this reason, lists are called mutable objects: it is possible to change part of a list (mutate it) rather than always returning a new list reflecting the intended modifications.

Moreover, since lists can share structure, changes to one list can sometimes affect others.

```
k := [1,2]
      [1,2]
```

Type: List PositiveInteger

```
m := cons(0,k)
      [0,1,2]
```

Type: List Integer

Change the second element of `m`.

```
m.2 := 99
      99
```

Type: PositiveInteger

See, `m` was altered.

```
m
      [0,99,2]
```

Type: List Integer

But what about `k`? It changed too!

```
k
[99,2]

Type: List PositiveInteger
```

Other Functions

An operation that is used frequently in list processing is that which returns all elements in a list after the first element.

```
k := [1,2,3]
[1,2,3]

Type: List PositiveInteger
```

Use the rest operation to do this.

```
rest k
[2,3]

Type: List PositiveInteger
```

To remove duplicate elements in a list k , use `removeDuplicates`.

```
removeDuplicates [4,3,4,3,5,3,4]
[4,3,5]

Type: List PositiveInteger
```

To get a list with elements in the order opposite to those in a list k , use `reverse`.

```
reverse [1,2,3,4,5,6]
[6,5,4,3,2,1]

Type: List PositiveInteger
```

To test whether an element is in a list, use `member?`: `member?(a,k)` returns true or false depending on whether a is in k or not.

```
member?(1/2, [3/4,5/6,1/2])
true

Type: Boolean
```

```
member?(1/12, [3/4,5/6,1/2])
false

Type: Boolean
```

We can get a list containing all but the last of the elements in a given non-empty list k .

```
reverse(rest(reverse(k)))
```

[1,2]

Type: List PositiveInteger

```
=====
Dot, Dot
=====
```

Certain lists are used so often that Axiom provides an easy way of constructing them. If n and m are integers, then `expand [n..m]` creates a list containing $n, n+1, \dots, m$. If $n > m$ then the list is empty. It is actually permissible to leave off the m in the dot-dot construction (see below).

The dot-dot notation can be used more than once in a list construction and with specific elements being given. Items separated by dots are called segments.

[1..3,10,20..23]

[1..3,10..10,20..23]

Type: List Segment PositiveInteger

Segments can be expanded into the range of items between the endpoints by using `expand`.

`expand [1..3,10,20..23]`

[1,2,3,10,20,21,22,23]

Type: List Integer

What happens if we leave off a number on the right-hand side of `..`?

`expand [1..]`

[1,2,3,4,5,6,7,8,9,10,...]

Type: Stream Integer

What is created in this case is a Stream which is a generalization of a list.

— domain LIST List —

```

)abbrev domain LIST List
++ Author: Michael Monagan
++ Date Created: Sep 1987
++ Description:

```

```

++ \spadtype{List} implements singly-linked lists that are
++ addressable by indices; the index of the first element
++ is 1. In addition to the operations provided by
++ \spadtype{IndexedList}, this constructor provides some
++ LISP-like functions such as \spadfun{null} and \spadfun{cons}.

```

```

List(S:Type): Exports == Implementation where
LISTMININDEX ==> 1      -- this is the minimum list index

```

```

Exports ==> ListAggregate S with
nil      : ()      -> %
  ++ nil() returns the empty list.
null     : %      -> Boolean
  ++ null(u) tests if list \spad{u} is the
  ++ empty list.
cons     : (S, %) -> %
  ++ cons(element,u) appends \spad{element} onto the front
  ++ of list \spad{u} and returns the new list. This new list
  ++ and the old one will share some structure.
append   : (%, %) -> %
  ++ append(u1,u2) appends the elements of list \spad{u1}
  ++ onto the front of list \spad{u2}. This new list
  ++ and \spad{u2} will share some structure.
if S has SetCategory then
  setUnion : (%, %) -> %
    ++ setUnion(u1,u2) appends the two lists u1 and u2, then
    ++ removes all duplicates. The order of elements in the
    ++ resulting list is unspecified.
  setIntersection : (%, %) -> %
    ++ setIntersection(u1,u2) returns a list of the elements
    ++ that lists \spad{u1} and \spad{u2} have in common.
    ++ The order of elements in the resulting list is unspecified.
  setDifference : (%, %) -> %
    ++ setDifference(u1,u2) returns a list of the elements
    ++ of \spad{u1} that are not also in \spad{u2}.

— domain LMOPS ListMonoidOps —

```

)abbrev domain LMOPS ListMonoidOps
++ Author: Manuel Bronstein
++ Date Created: November 1989
++ Date Last Updated: 6 June 1991
++ Description:
++ This internal package represents monoid (abelian or not, with or
++ without inverses) as lists and provides some common operations
++ to the various flavors of monoids.

```

```

ListMonoidOps(S, E, un): Exports == Implementation where
  S : SetCategory
  E : AbelianMonoid
  un: E

```

```

REC ==> Record(gen:S, exp: E)
0    ==> OutputForm

```

```

Exports ==> Join(SetCategory, RetractableTo S) with
  outputForm : ($, (0, 0) -> 0, (0, 0) -> 0, Integer) -> 0

```

```

++ outputForm(l, fop, fexp, unit) converts the monoid element
++ represented by l to an \spadtype{OutputForm}.
++ Argument unit is the output form
++ for the \spadignore{unit} of the monoid (e.g. 0 or 1),
++ \spad{fop(a, b)} is the
++ output form for the monoid operation applied to \spad{a} and b
++ (e.g. \spad{a + b}, \spad{a * b}, \spad{ab}),
++ and \spad{fexp(a, n)} is the output form
++ for the exponentiation operation applied to \spad{a} and n
++ (e.g. \spad{n a}, \spad{n * a}, \spad{a ** n}, \spad{a^~n}).
listOfMonoms : $ -> List REC
++ listOfMonoms(l) returns the list of the monomials forming l.
makeTerm      : (S, E) -> $
++ makeTerm(s, e) returns the monomial s exponentiated by e
++ (e.g. s^e or e * s).
makeMulti     : List REC -> $
++ makeMulti(l) returns the element whose list of monomials is l.
nthExpon      : ($, Integer) -> E
++ nthExpon(l, n) returns the exponent of the n^th monomial of l.
nthFactor     : ($, Integer) -> S
++ nthFactor(l, n) returns the factor of the n^th monomial of l.
reverse       : $ -> $
++ reverse(l) reverses the list of monomials forming l. This
++ has some effect if the monoid is non-abelian, i.e.
++ \spad{reverse(a1^~e1 ... an^~en) = an^~en ... a1^~e1} which is different.
reverse_!     : $ -> $
++ reverse!(l) reverses the list of monomials forming l, destroying
++ the element l.
size          : $ -> NonNegativeInteger
++ size(l) returns the number of monomials forming l.
makeUnit      : () -> $
++ makeUnit() returns the unit element of the monomial.
rightMult     : ($, S) -> $
++ rightMult(a, s) returns \spad{a * s} where \spad{*}
++ is the monoid operation,
++ which is assumed non-commutative.
leftMult      : (S, $) -> $
++ leftMult(s, a) returns \spad{s * a} where
++ \spad{*} is the monoid operation,
++ which is assumed non-commutative.
plus          : (S, E, $) -> $
++ plus(s, e, x) returns \spad{e * s + x} where \spad{+}
++ is the monoid operation,
++ which is assumed commutative.
plus          : ($, $) -> $
++ plus(x, y) returns \spad{x + y} where \spad{+}
++ is the monoid operation,
++ which is assumed commutative.
commutativeEquality: ($, $) -> Boolean
++ commutativeEquality(x,y) returns true if x and y are equal

```

```

    ++ assuming commutativity
mapExpon      : (E -> E, $) -> $
    ++ mapExpon(f, a1\^e1 ... an\^en) returns \spad{a1\^f(e1) ... an\^f(en)}.
mapGen        : (S -> S, $) -> $
    ++ mapGen(f, a1\^e1 ... an\^en) returns \spad{f(a1)\^e1 ... f(an)\^en}.

=====

LyndonWord examples

=====

A function f in $[0,1]$ is called acyclic if $C(F)$ consists of n

different objects. The canonical representative of the orbit of an acyclic function is usually called a Lyndon Word. If f is acyclic, then all elements in the orbit $C(f)$ are acyclic as well, and we call $C(f)$ an acyclic orbit.

++ Author: Michel Petitot (petitot@lifl.fr).
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Fix History: compilation v 2.1 le 13 dec 98
++ References:
++ Free Lie Algebras by C. Reutenauer (Oxford science publications).
++ Description:
++ Lyndon words over arbitrary (ordered) symbols:
++ see Free Lie Algebras by C. Reutenauer (Oxford science publications).
++ A Lyndon word is a word which is smaller than any of its right factors
++ w.r.t. the pure lexicographical ordering.
++ If \axiom{a} and \axiom{b} are two Lyndon words such that \axiom{a < b}
++ holds w.r.t lexicographical ordering then \axiom{a*b} is a Lyndon word.
++ Parenthesized Lyndon words can be generated from symbols by using the
++ following rule:\br
++ \axiom{[[a,b],c]} is a Lyndon word iff \axiom{a*b < c <= b} holds.\br
++ Lyndon words are internally represented by binary trees using the
++ \spadtype{Magma} domain constructor.
++ Two ordering are provided: lexicographic and
++ length-lexicographic.

=====
MathMLFormat examples
=====
```

This package is based on the TeXFormat domain by Robert S. Sutor
 MathMLFormat provides a coercion from OutputForm to MathML format.

See Also:

o)show MathMLFormat

Both this code and documentation are still under development and I don't pretend they are anywhere close to perfect or even finished. However the code does work and I hope it might be useful to somebody both for it's ability to output MathML from Axiom and as an example of how to write a new output form.

Introduction to Mathematical Markup Language

MathML exists in two forms: presentation and content. At this time (2007-02-11) the package only has a presentation package. A content package is in the works however it is more difficult. Unfortunately Axiom does not make its semantics easily available. The `OutputForm` domain mediates between the individual Axiom domains and the user visible output but `OutputForm` does not provide full semantic information. From my currently incomplete understanding of Axiom it appears that remedying this would entail going back to the individual domains and rewriting a lot of code. However some semantics are conveyed directly by `OutputForm` and other things can be deduced from `OutputForm` or from the original user command.

Displaying MathML

The MathML string produced by `)set output mathml on` can be pasted directly into an appropriate xhtml page and then viewed in Firefox or some other MathML aware browser. The boiler plate code needed for a test page, `testmathml.xml`, is:

```
<?xml version="1.0" ?>
```

```

<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1 plus MathML 2.0//EN"
    "http://www.w3.org/Math/DTD/mathml2/xhtml-math11-f.dtd" [
<!ENTITY mathml "http://www.w3.org/1998/Math/MathML">
]>

<html xmlns="http://www.w3.org/1999/xhtml"
    xmlns:xlink="http://www.w3.org/1999/xlink" >

    <head>
        <title>MathML Test </title>
    </head>

    <body>

    </body>
</html>

```

Paste the MathML string into the body element and it should display nicely in Firefox.

Test Cases

Here's a list of test cases that currently format correctly:

1. $(x+y)^{**2}$
2. $\text{integrate}(x^{**x}, x)$
3. $\text{integral}(x^{**x}, x)$
4. $(5 + \sqrt{63} + \sqrt{847})^{**}(1/3)$
5. $\text{set } [1, 2, 3]$
6. $\text{multiset } [x \bmod 5 \text{ for } x \text{ in primes}(2, 1000)]$
7. $\text{series}(\sin(a \cdot x), x=0)$
8. $\text{matrix } [[x^{**i} + y^{**j} \text{ for } i \text{ in } 1..10] \text{ for } j \text{ in } 1..10]$
9. $y := \text{operator } 'y \text{ a. } D(y(x, z), [x, x, z, x]) \text{ b. } D(y \ x, x, 2)$
10. $x := \text{series } 'x \text{ a. } \sin(1+x)$
11. $\text{series}(1/\log(y), y=1)$
12. $y:\text{UTS}(\text{FLOAT}, 'z, 0) := \exp(z)$
13. a. $c := \text{continuedFraction}(314159/100000)$ b. $c := \text{continuedFraction}(314159/100000)$

The `TexFormat` domain has the capability to format an object with subscripts, superscripts, presubscripts and presuperscripts however I don't know of any Axiom command that produces such an object. In fact at present I see the case of "SUPERSUB" being used for putting primes in the superscript position to denote ordinary differentiation. I also only see the "SUB" case being used to denote partial derivatives.

)set output mathml on

Making mathml appear as output during a normal Axiom session by invoking ")set output mathml on" proved to be a bit tedious and seems to be undocumented. I document my experience here in case it proves useful to somebody else trying to get a new output format from Axiom.

In MathMLFormat the functions **coerce(expr : OutputForm) : String** and **display(s : String) : Void** provide the desired mathml output. Note that this package was constructed by close examination of Robert Sutor's **TexFormat** domain and much remains from that source. To have mathml displayed as output we need to get Axiom to call **display(coerce(expr))** at the appropriate place. Here's what I did to get that to happen. Note that my starting point here was an attempt by Andrey Grozin to do the same. To figure things out I searched through files for "tex" to see what was done for the **TexFormat** domain, and used **grep** to find which files had mention of **TexFormat**.

File src/interp/setvars.boot.pamphlet

Create an output mathml section by analogy to the tex section. Remember to add the code chunk "outputmathmlCode" at the end.

setvars.boot is a bootstrap file which means that it has to be precompiled into lisp code and then that code has to be inserted back into setvars.boot. To do this extract the boot code by running "notangle" on it. I did this from the "tmp" directory. From inside axiom run ")lisp (boottran::boottool "tmp/setvars.boot")" which put "setvars.clisp" into "int/interp/setvars.clisp". Then replace the lisp in "setvars.boot.pamphlet" with that in the newly generated "setvars.clisp".

The relevant code chunks appearing in "setvars.boot.pamphlet" are:

```
outputmathmlCode
setOutputMathml
describeSetOutputMathml
```

and the relevant variables are:

```
setOutputMathml
$mathmlOutputStream
$mathmlOutputFile
$mathmlFormat
describeSetOutputMathml
```

File setvart.boot.pamphlet

Create an output mathml section in "setvart.boot.pamphlet" again patterned after the tex section. I changed the default file extension from ".stex" to ".smml".

To the "sectionoutput" table I added the line

```
mathml                                created output in MathML style      Off:CONSOLE
```

Added the code chunk "outputmathml" to the code chunk "output" in "sectionoutput".

Relevant code chunks:

```
outputmathml
```

Relevant variables:

```
setOutputMathml
$mathmlFormat
$mathmlOutputFile
```

Note when copying the tex stuff I changed occurrences of "tex" to "mathml", "Tex" to "Mathml" and "TeX" to "MathML".

File src/algebra/Makefile.pamphlet

The file "src/algebra/tex.spad.pamphlet" contains the domain `TexFormat` (TEX) and the package `TexFormat1` (TEX1). However the sole function of `TexFormat1` is to **coerce** objects from a domain into `OutputForm` and then apply `TexFormat` to them. It is to save programmers the trouble of doing the coercion themselves from inside spad code. It does not appear to be used for the main purpose of delivering Axiom output in TeX format. In order to keep the mathml package as simple as possible, and because I didn't see much use for this, I didn't copy the `TexFormat1` package. So no analog of the TEX1 entries in "Makefile.pamphlet" were needed. One curiosity I don't understand is why TEX1 appears in layer 4 when it seems to depend on TEX which appears in layer 14.

Initially I added "\$OUT/MMLFORM.o" to layer 14 and "mathml.spad.pamphlet" to completed spad files in layer 14. When trying to compile the build failed at MMLFORM. It left "MMLFORM.erlib" in "int/algebra" instead of "MMLFORM.NRLIB" which confused me at first because mathml.spad compiled under a running axiom. By examining the file "obj/tmp/trace" I saw that a new dependency had been introduced, compared to `TexFormat`, with the function `eltName` depending on the domain `FSAGG` in layer 16. So the lines had to be moved from layer 14 to layer 17.

Added appropriate lines to "SPADFILES" and "DOCFILES".

File src/algebra/exposed.lsp.pamphlet

Add the line "(|MathMLFormat| . MMLFORM)"

File src/algebra/Lattice.pamphlet

I don't see that this file is used anywhere but I made the appropriate changes anyway by searching for "TEX" and mimicing everything for MMLFORM.

File `src/doc/axiom.bib.pamphlet`

Added `mathml.spad` subsection to `"src/doc/axiom.bib.pamphlet"`.

File `interp/i-output.boot.pamphlet`

This is where the **coerce** and **display** functions from `MathMLFormat` actually get called. The following was added:

```
mathmlFormat expr ==
  mml := '(MathMLFormat)
  mmlrep := '(String)
  formatFn := getFunctionFromDomain("coerce",mml,[$OutputForm])
  displayFn := getFunctionFromDomain("display",mml,[mmlrep])
  SPADCALL(SPADCALL(expr,formatFn),displayFn)
  TERPRI $mathmlOutputStream
  FORCE_-OUTPUT $mathmlOutputStream
  NIL
```

Note that compared to the `texFormat` function there are a couple of differences. Since `MathMLFormat` is currently a package rather than a domain there is the `"mmlrep"` variable whereas in `texFormat` the argument of the `"display"` function is an instance of the domain. Also the **coerce** function here only has one argument, namely `"$OutputForm"`.

Also for the function `"output(expr,domain)"` add lines for `mathml`, e.g. `"if $mathmlFormat then mathmlFormat expr"`.

After these changes Axiom compiled with `mathml` enabled under `)set output`.

Public Declarations

The declarations

```
E      ==> OutputForm
I      ==> Integer
L      ==> List
S      ==> String
US     ==> UniversalSegment(Integer)
```

provide abbreviations for domains used heavily in the code. The publicly exposed functions are:

coerce: E -> S This function is the main one for converting an expression in domain `OutputForm` into a MathML string.

coerceS: E -> S This function is for use from the command line. It converts an `OutputForm` expression into a MathML string and does some formatting so that the output is not one long line. If you take the output from this function, stick it in an emacs buffer in `nxml-mode`

and then indent according to mode, you'll get something that's nicer to look at than what comes from `coerce`. Note that `coerceS` returns the same value as `coerce` but invokes a display function as well so that the result will be printed twice in different formats. The need for this is that the output from `coerce` is automatically formatted with line breaks by Axiom's output routine that are not in the right place.

coerceL: E -> S Similar to `coerceS` except that the displayed result is the MathML string in one long line. These functions can be used, for instance, to get the MathML for the previous result by typing `coerceL(`

expres: E -> S Converts `OutputForm` to `String` with the structure preserved with braces. This is useful in developing this package. Actually this is not quite accurate. The function **precondition** is first applied to the `OutputForm` expression before **expres**. Raw `OutputForm` and the nature of the **precondition** function is still obscure to me at the time of this writing (2007-02-14), however I probably need to understand it to make sure I'm not missing any semantics. The `spad` function **precondition** is just a wrapper for the lisp function `outputTran$Lisp`, which I guess is compiled from `boot`.

display: S -> Void This one prints the string returned by `coerce` as one long line, adding "math" tags: `$...$`. Thus the output from this can be stuck directly into an appropriate `html/xhtml` page and will be displayed nicely by a MathML aware browser.

displayF: S -> Void This function doesn't exist yet but it would be nice to have a humanly readable formatted output as well. The basics do exist in the `coerceS` function however the formatting still needs some work to be really good.

— public declarations —

```
)abbrev domain MMLFORM MathMLFormat
++ Author: Arthur C. Ralfs
++ Date: January 2007
++ Description:
++ This package is based on the TeXFormat domain by Robert S. Sutor
++ \spadtype{MathMLFormat} provides a coercion from \spadtype{OutputForm}
++ to MathML format.
```

```
MathMLFormat(): public == private where
```

```
  E      ==> OutputForm
  I      ==> Integer
  L      ==> List
  S      ==> String
  US     ==> UniversalSegment(Integer)
```

```
public == SetCategory with
```

```
  coerce:   E -> S
    ++ coerceS(o) changes o in the standard output format to MathML
    ++ format.
  coerceS:  E -> S
    ++ coerceS(o) changes o in the standard output format to MathML
    ++ format and displays formatted result.
```

```

coerceL:  E -> S
  ++ coerceS(o) changes o in the standard output format to MathML
  ++ format and displays result as one long string.
expres:   E -> S
  ++ converts \spadtype{OutputForm} to \spadtype{String} with the
  ++ structure preserved with braces.  Actually this is not quite
  ++ accurate.  The function \spadfun{precondition} is first
  ++ applied to the
  ++ \spadtype{OutputForm} expression before \spadfun{expres}.
  ++ The raw \spadtype{OutputForm} and
  ++ the nature of the \spadfun{precondition} function is
  ++ still obscure to me
  ++ at the time of this writing (2007-02-14).
display:  S -> Void
  ++ prints the string returned by coerce, adding <math ...> tags.

```

Private Function Declarations

These are the local functions:

addBraces:S -> S

addBrackets:S -> S

atomize:E -> L E

displayElt:S -> Void function for recursively displaying mathml nicely formatted

eltLimit:(S,I,S) -> I demarcates end postion of mathml element with name:S starting at position i:I in mathml string s:S and returns end of end tag as i:I position in mathml string, i.e. find start and end of substring: <name ...>...</name>

eltName:(I,S) -> S find name of mathml element starting at position i:I in string s:S

group:S -> S

formatBinary:(S,L E, I) -> S

formatFunction:(S,L E, I) -> S

formatMatrix:L E -> S

```

formatNary:(S,L E, I) -> S
formatNaryNoGroup:(S,L E, I) -> S
formatNullary:S -> S
formatPlex:(S,L E, I) -> S
formatSpecial:(S,L E, I) -> S
formatUnary:(S, E, I) -> S
formatMml:(E,I) -> S
newWithNum:I -> $ this is a relic from tex.spad and is not used here so far. I'll probably
remove it.
parenthesize:S -> S
precondition:E -> E this function is applied to the OutputForm expression before doing
anything else.
postcondition:S -> S this function is applied after all other OutputForm -> MathML trans-
formations. In the TexFormat domain the ungroup function first peels off the outermost set
of braces however I have replaced braces with <mrow>s here and sometimes the outermost
set of <mrow>s is necessary to get proper display in Firefox. For instance with getting the
correct size of brackets on a matrix the whole expression needs to be enclosed in a mrow
element. It also checks for +- and removes the +.
stringify:E -> S
tagEnd:(S,I,S) -> I finds closing ">" of start or end tag for mathML element for formatting
MathML string for human readability. No analog in TexFormat.
ungroup:S -> S

```

Public Function Definitions

Note that I use the function `sayTeX$Lisp` much as I would `printf` in a C program. I've noticed in grepping the code that there are other "say" functions, `sayBrightly` and `sayMessage` for instance, but I have no idea what the difference is between them at this point. `sayTeX$Lisp` does the job so for the time being I'll use that until I learn more.

The functions `coerceS` and `coerceL` should probably be changed to display functions, *i.e.* **`displayS`** and **`display L`**, returning `Void`. I really only need the one `coerce` function.

```

Formatting Functions

Still need to format `\zag` in `formatSpecial`!

In `formatPlex` the case `op = "INTSIGN"` is now passed off to `formatIntSign` which is a change from the `TexFormat` domain. This is done here for presentation mark up to replace the ugly bound variable that Axiom delivers. For content mark up this has to be done anyway.

The `formatPlex` function also allows for `op = "INDEFINTEGRAL"`. However I don't know what Axiom command gives rise to this case. The `INTSIGN` case already allows for both definite and indefinite integrals.

In the function `formatSpecial` various cases are handled including `SUB` and `SUPERSUB`. These cases are now caught in `formatMml` and so the code in `formatSpecial` doesn't get executed. The only cases I know of using these are partial derivatives for `SUB` and ordinary derivatives or `SUPERSUB` however in `TexFormat` the capability is there to handle multi-scripts, i.e. an object with subscripts, superscripts, pre-subscripts and pre-superscripts but I am so far unaware of any Axiom command that produces such a multiscripted object.

Another question is how to represent derivatives. At present I have differential notation for partials and prime notation for ordinary derivatives, but it would be nice to allow for different derivative notations in different circumstances, maybe some options to `)set output mathml on`.

Ordinary derivatives are formatted in `formatSuperSub` and there are 2 versions, `formatSuperSub` and `formatSuperSub1`, which at this point have to be switched by swapping names.

=====

MathMLFormat examples

=====

MathML is an HTML-like markup language for mathematics. It uses the "knuckle" syntax of HTML such as "<mo>" to introduce a math operator and "</mo>" to mark the end of the operator. Axiom can generate MathML output and does so when it communicates to the browser front end.

This output is enabled by

```
)set output mathml on
```

after which you'll see the MathML markup as well as the algebra.
Note that you can turn off the algebra output with

```
)set output algebra off
```

but we don't do that here so you can compare the output.

— Matrix.help —

=====

Matrix examples

=====

The Matrix domain provides arithmetic operations on matrices and standard functions from linear algebra. This domain is similar to the TwoDimensionalArray domain, except that the entries for Matrix must belong to a Ring.

=====

Creating Matrices

=====

There are many ways to create a matrix from a collection of values or from existing matrices.

If the matrix has almost all items equal to the same value, use new to create a matrix filled with that value and then reset the entries that are different.

```

m : Matrix(Integer) := new(3,3,0)
+0  0  0+
|    |
|0  0  0|
|    |
+0  0  0+
Type: Matrix Integer

```

To change the entry in the second row, third column to 5, use `setelt`.

```

setelt(m,2,3,5)
5
Type: PositiveInteger

```

An alternative syntax is to use assignment.

```

m(1,2) := 10
10
Type: PositiveInteger

```

The matrix was destructively modified.

```

m
+0  10  0+
|    |
|0  0  5|
|    |
+0  0  0+
Type: Matrix Integer

```

If you already have the matrix entries as a list of lists, use `matrix`.

```

matrix [ [1,2,3,4],[0,9,8,7] ]
+1  2  3  4+
|    |
+0  9  8  7+
Type: Matrix Integer

```

If the matrix is diagonal, use `diagonalMatrix`.

```

dm := diagonalMatrix [1,x**2,x**3,x**4,x**5]
+1  0  0  0  0 +
|    |
|  2  |
|0  x  0  0  0 |
|    |
|  3  |
|0  0  x  0  0 |
|    |
|  4  |

```

```

|0 0 0 x 0|
|          |
|          5|
+0 0 0 0 x+
Type: Matrix Polynomial Integer

```

Use `setRow` and `setColumn` to change a row or column of a matrix.

```

setRow!(dm,5,vector [1,1,1,1,1])
+1 0 0 0 0+
|          |
|      2    |
|0 x 0 0 0|
|          |
|      3    |
|0 0 x 0 0|
|          |
|      4    |
|0 0 0 x 0|
|          |
+1 1 1 1 1+
Type: Matrix Polynomial Integer

```

```

setColumn!(dm,2,vector [y,y,y,y,y])
+1 y 0 0 0+
|          |
|0 y 0 0 0|
|          |
|      3    |
|0 y x 0 0|
|          |
|      4    |
|0 y 0 x 0|
|          |
+1 y 1 1 1+
Type: Matrix Polynomial Integer

```

Use `copy` to make a copy of a matrix.

```

cdm := copy(dm)
+1 y 0 0 0+
|          |
|0 y 0 0 0|
|          |
|      3    |
|0 y x 0 0|
|          |
|      4    |
|0 y 0 x 0|
|          |

```

```
+1 y 1 1 1+
Type: Matrix Polynomial Integer
```

This is useful if you intend to modify a matrix destructively but want a copy of the original.

```
setelt(dm,4,1,1-x**7)
7
- x + 1
Type: Polynomial Integer
```

```
[dm,cdm]
+ 1 y 0 0 0+ +1 y 0 0 0+
| | | |
| 0 y 0 0 0| |0 y 0 0 0|
| | | |
| 3 | | 3 |
[| 0 y x 0 0| |0 y x 0 0|]
| | | |
| 7 4 | | 4 |
|- x + 1 y 0 x 0| |0 y 0 x 0|
| | | |
+ 1 y 1 1 1+ +1 y 1 1 1+
Type: List Matrix Polynomial Integer
```

Use `subMatrix` to extract part of an existing matrix. The syntax is `subMatrix(m, firstrow, lastrow, firstcol, lastcol)`.

```
subMatrix(dm,2,3,2,4)
+y 0 0+
| |
| 3 |
+y x 0+
Type: Matrix Polynomial Integer
```

To change a submatrix, use `setsubMatrix`.

```
d := diagonalMatrix [1.2,-1.3,1.4,-1.5]
+1.2 0.0 0.0 0.0 +
| |
|0.0 - 1.3 0.0 0.0 |
| |
|0.0 0.0 1.4 0.0 |
| |
+0.0 0.0 0.0 - 1.5+
Type: Matrix Float
```

If `e` is too big to fit where you specify, an error message is displayed. Use `subMatrix` to extract part of `e`, if necessary.

```
e := matrix [ [6.7,9.11],[-31.33,67.19] ]
+ 6.7    9.11 +
|          |
+- 31.33  67.19+
Type: Matrix Float
```

This changes the submatrix of d whose upper left corner is at the first row and second column and whose size is that of e.

```
setsubMatrix!(d,1,2,e)
+1.2    6.7    9.11    0.0 +
|          |          |
|0.0   - 31.33  67.19    0.0 |
|          |          |
|0.0    0.0    1.4    0.0 |
|          |          |
+0.0    0.0    0.0   - 1.5+
Type: Matrix Float
```

```
d
+1.2    6.7    9.11    0.0 +
|          |          |
|0.0   - 31.33  67.19    0.0 |
|          |          |
|0.0    0.0    1.4    0.0 |
|          |          |
+0.0    0.0    0.0   - 1.5+
Type: Matrix Float
```

Matrices can be joined either horizontally or vertically to make new matrices.

```
a := matrix [ [1/2,1/3,1/4],[1/5,1/6,1/7] ]
+1  1  1+
|- - -|
|2  3  4|
|    |
|1  1  1|
|- - -|
+5  6  7+
Type: Matrix Fraction Integer
```

```
b := matrix [ [3/5,3/7,3/11],[3/13,3/17,3/19] ]
+3  3  3+
|- - --|
|5  7  11|
|    |
| 3  3  3|
|-- -- --|
+13 17 19+
```

Type: Matrix Fraction Integer

Use `horizConcat` to append them side to side. The two matrices must have the same number of rows.

```
horizConcat(a,b)
+1  1  1  3  3  3+
|-  -  -  -  -  --|
|2  3  4  5  7  11|
|
|1  1  1  3  3  3|
|-  -  -  --  --  --|
+5  6  7  13 17 19+
```

Type: Matrix Fraction Integer

Use `vertConcat` to stack one upon the other. The two matrices must have the same number of columns.

```
vab := vertConcat(a,b)
+1  1  1  +
|-  -  -  |
|2  3  4  |
|
|1  1  1  |
|-  -  -  |
|5  6  7  |
|
|3  3  3  |
|-  -  --  |
|5  7  11|
|
| 3  3  3|
|--  --  --|
+13 17 19+
```

Type: Matrix Fraction Integer

The operation `transpose` is used to create a new matrix by reflection across the main diagonal.

```
transpose vab
+1  1  3  3+
|-  -  -  --|
|2  5  5  13|
|
|1  1  3  3|
|-  -  -  --|
|3  6  7  17|
|
|1  1  3  3|
|-  -  --  --|
```

```
+4  7  11  19+
```

```
Type: Matrix Fraction Integer
```

```
=====
Operations on Matrices
=====
```

Axiom provides both left and right scalar multiplication.

```
m := matrix [ [1,2],[3,4] ]
```

```
+1  2+
```

```
|  |
```

```
+3  4+
```

```
Type: Matrix Integer
```

```
4 * m * (-5)
```

```
+-- 20  - 40+
```

```
|  |
```

```
+-- 60  - 80+
```

```
Type: Matrix Integer
```

You can add, subtract, and multiply matrices provided, of course, that the matrices have compatible dimensions. If not, an error message is displayed.

```
n := matrix([ [1,0,-2],[-3,5,1] ])
```

```
+ 1  0  - 2+
```

```
|  |
```

```
+-- 3  5  1 +
```

```
Type: Matrix Integer
```

This following product is defined but $n * m$ is not.

```
m * n
```

```
+-- 5  10  0 +
```

```
|  |
```

```
+-- 9  20  - 2+
```

```
Type: Matrix Integer
```

The operations `nrows` and `ncols` return the number of rows and columns of a matrix. You can extract a row or a column of a matrix using the operations `row` and `column`. The object returned is a Vector.

Here is the third column of the matrix `n`.

```
vec := column(n,3)
```

```
[- 2,1]
```

```
Type: Vector Integer
```

You can multiply a matrix on the left by a "row vector" and on the right

by a "column vector".

```
vec * m
[1,0]
```

Type: Vector Integer

Of course, the dimensions of the vector and the matrix must be compatible or an error message is returned.

```
m * vec
[0,- 2]
```

Type: Vector Integer

The operation `inverse` computes the inverse of a matrix if the matrix is invertible, and returns "failed" if not.

This Hilbert matrix is invertible.

```
hilb := matrix([ [1/(i + j) for i in 1..3] for j in 1..3])
+1 1 1+
|- - -|
|2 3 4|
|   |
|1 1 1|
|- - -|
|3 4 5|
|   |
|1 1 1|
|- - -|
+4 5 6+
```

Type: Matrix Fraction Integer

```
inverse(hilb)
+ 72 - 240 180 +
|   |
|- 240 900 - 720|
|   |
+ 180 - 720 600 +
Type: Union(Matrix Fraction Integer,...)
```

This matrix is not invertible.

```
mm := matrix([ [1,2,3,4], [5,6,7,8], [9,10,11,12], [13,14,15,16] ])
+1 2 3 4 +
|   |
|5 6 7 8|
|   |
|9 10 11 12|
|   |
+13 14 15 16+
```

Type: Matrix Integer

```
inverse(mm)
"failed"
```

Type: Union("failed",...)

The operation determinant computes the determinant of a matrix provided that the entries of the matrix belong to a CommutativeRing.

The above matrix mm is not invertible and, hence, must have determinant 0.

```
determinant(mm)
0
```

Type: NonNegativeInteger

The operation trace computes the trace of a square matrix.

```
trace(mm)
34
```

Type: PositiveInteger

The operation rank computes the rank of a matrix: the maximal number of linearly independent rows or columns.

```
rank(mm)
2
```

Type: PositiveInteger

The operation nullity computes the nullity of a matrix: the dimension of its null space.

```
nullity(mm)
2
```

Type: PositiveInteger

The operation nullSpace returns a list containing a basis for the null space of a matrix. Note that the nullity is the number of elements in a basis for the null space.

```
nullSpace(mm)
[[1,- 2,1,0],[2,- 3,0,1]]
```

Type: List Vector Integer

The operation rowEchelon returns the row echelon form of a matrix. It is easy to see that the rank of this matrix is two and that its nullity is also two.

```
rowEchelon(mm)
+1  2  3  4 +
|          |
```

```

|0  4  8 12|
|          |
|0  0  0  0|
|          |
+0  0  0  0 +

```

Type: Matrix Integer

— domain MATRIX Matrix —

```

)abbrev domain MATRIX Matrix
++ Author: Grabmeier, Gschnitzer, Williamson
++ Date Created: 1987
++ Date Last Updated: July 1990
++ Description:
++ \spadtype{Matrix} is a matrix domain where 1-based indexing is used
++ for both rows and columns.

Matrix(R): Exports == Implementation where
  R : Ring
  Row ==> Vector R
  Col ==> Vector R
  mnRow ==> 1
  mnCol ==> 1
  MATLIN ==> MatrixLinearAlgebraFunctions(R,Row,Col,$)
  MATSTOR ==> StorageEfficientMatrixOperations(R)

Exports ==> MatrixCategory(R,Row,Col) with
  diagonalMatrix: Vector R -> $
  ++ \spad{diagonalMatrix(v)} returns a diagonal matrix where the elements
  ++ of v appear on the diagonal.

  if R has ConvertibleTo InputForm then ConvertibleTo InputForm

  if R has Field then
    inverse: $ -> Union($,"failed")
    ++ \spad{inverse(m)} returns the inverse of the matrix m.
    ++ If the matrix is not invertible, "failed" is returned.
    ++ Error: if the matrix is not square.
--  matrix: Vector Vector R -> $
--  ++ \spad{matrix(v)} converts the vector of vectors v to a matrix, where

```

```
--      ++ the vector of vectors is viewed as a vector of the rows of the
--      ++ matrix
--      diagonalMatrix: Vector $ -> $
--      ++ \spad{diagonalMatrix([m1,...,mk])} creates a block diagonal matrix
--      ++ M with block matrices m1,...,mk down the diagonal,
--      ++ with 0 block matrices elsewhere.
--      vectorOfVectors: $ -> Vector Vector R
--      ++ \spad{vectorOfVectors(m)} returns the rows of the matrix m as a
--      ++ vector of vectors
```

Implementation ==>

```
InnerIndexedTwoDimensionalArray(R,mnRow,mnCol,Row,Col) add
  minr ==> minRowIndex
  maxr ==> maxRowIndex
  minc ==> minColIndex
  maxc ==> maxColIndex
  mini ==> minIndex
  maxi ==> maxIndex

=====

MonoidRing examples

=====

MonoidRing(R,M), implements the algebra of all maps from the monoid M to the commutative ring R with finite support.

Multiplication of two maps f and g is defined to map an element c of M to the (convolution) sum over f(a)g(b) such that ab = c. Thus M can be identified with a canonical basis and the maps can also be considered as formal linear combinations of the elements in M. Scalar multiples of a basis element are called monomials. A prominent example is the class of polynomials where the monoid is a direct product of the natural numbers with pointwise addition. When M is FreeMonoid Symbol, one gets polynomials in infinitely many non-commuting variables. Another application area is representation theory of finite groups G, where modules over MonoidRing(R,G) are studied.

)abbrev domain MRING MonoidRing
++ Authors: Stephan M. Watt; revised by Johannes Grabmeier
++ Date Created: January 1986
++ Date Last Updated: 14 December 1995, Mike Dewar
++ Description:
++ \spadtype{MonoidRing}(R,M), implements the algebra
++ of all maps from the monoid M to the commutative ring R with
++ finite support.
++ Multiplication of two maps f and g is defined
++ to map an element c of M to the (convolution) sum over f(a)g(b)
++ such that ab = c. Thus M can be identified with a canonical
++ basis and the maps can also be considered as formal linear combinations
++ of the elements in M. Scalar multiples of a basis element are called
++ monomials. A prominent example is the class of polynomials
++ where the monoid is a direct product of the natural numbers
++ with pointwise addition. When M is
++ \spadtype{FreeMonoid Symbol}, one gets polynomials
++ in infinitely many non-commuting variables. Another application
++ area is representation theory of finite groups G, where modules
++ over \spadtype{MonoidRing}(R,G) are studied.

Multiset examples

=====

The domain Multiset(R) is similar to Set(R) except that multiplicities (counts of duplications) are maintained and displayed. Use the operation multiset to create multisets from lists. All the standard operations from sets are available for multisets. An element with multiplicity greater than one has the multiplicity displayed first, then a colon, and then the element.

Create a multiset of integers.

```

s := multiset [1,2,3,4,5,4,3,2,3,4,5,6,7,4,10]
{1,2: 2,3: 3,4: 4,2: 5,6,7,10}
Type: Multiset PositiveInteger

```

The operation insert! adds an element to a multiset.

```

insert!(3,s)
{1,2: 2,4: 3,4: 4,2: 5,6,7,10}
Type: Multiset PositiveInteger

```

Use remove! to remove an element. If a third argument is present, it specifies how many instances to remove. Otherwise all instances of the element are removed. Display the resulting multiset.

```

remove!(3,s,1); s
{1,2: 2,3: 3,4: 4,2: 5,6,7,10}
Type: Multiset PositiveInteger

```

```
remove!(5,s); s
{1,2: 2,3: 3,4: 4,6,7,10}
Type: Multiset PositiveInteger
```

The operation count returns the number of copies of a given value.

```
count(5,s)
0
Type: NonNegativeInteger
```

A second multiset.

```
t := multiset [2,2,2,-9]
{3: 2,- 9}
Type: Multiset Integer
```

The union of two multisets is additive.

```
U := union(s,t)
{1,5: 2,3: 3,4: 4,6,7,10,- 9}
Type: Multiset Integer
```

The intersect operation gives the elements that are in common, with additive multiplicity.

```
I := intersect(s,t)
{5: 2}
Type: Multiset Integer
```

The difference of s and t consists of the elements that s has but t does not. Elements are regarded as indistinguishable, so that if s and t have any element in common, the difference does not contain that element.

```
difference(s,t)
{1,3: 3,4: 4,6,7,10}
Type: Multiset Integer
```

The symmetricDifference is the union of difference(s, t) and difference(t, s).

```
S := symmetricDifference(s,t)
{1,3: 3,4: 4,6,7,10,- 9}
Type: Multiset Integer
```

Check that the union of the symmetricDifference and the intersect equals the union of the elements.

```
(U = union(S,I))@Boolean
true
Type: Boolean
```

Check some inclusion relations.

```
t1 := multiset [1,2,2,3]; [t1 < t, t1 < s, t < s, t1 <= s]
[false,true,false,true]
Type: List Boolean
```

=====

MultivariatePolynomial examples

=====

The domain constructor `MultivariatePolynomial` is similar to `Polynomial` except that it specifies the variables to be used. `Polynomial` are available for `MultivariatePolynomial`. The abbreviation for `MultivariatePolynomial` is `MPOLY`. The type expressions

```

MultivariatePolynomial([x,y],Integer)
MPOLY([x,y],INT)

```

refer to the domain of multivariate polynomials in the variables x and y where the coefficients are restricted to be integers. The first variable specified is the main variable and the display of the polynomial reflects this.

This polynomial appears with terms in descending powers of the variable x .

```
m : MPOLY([x,y],INT) := (x^2 - x*y^3 + 3*y)^2
      4      3 3      6      2      4      2
      x  - 2y x  + (y  + 6y)x  - 6y x + 9y
      Type: MultivariatePolynomial([x,y],Integer)
```

It is easy to see a different variable ordering by doing a conversion.

```
m :: MPOLY([y,x],INT)
      2 6      4      3 3      2      2      4
      x y  - 6x y  - 2x y  + 9y  + 6x y + x
      Type: MultivariatePolynomial([y,x],Integer)
```

You can use other, unspecified variables, by using `Polynomial` in the coefficient type of `MPOLY`.

```
p : MPOLY([x,y],POLY INT)
      Type: Void
```

Conversions can be used to re-express such polynomials in terms of the other variables. For example, you can first push all the variables into a polynomial with integer coefficients.

```
p :: POLY INT
p
      Type: Polynomial Integer
```

Now pull out the variables of interest.

```
% :: MPOLY([a,b],POLY INT)
p
      Type: MultivariatePolynomial([a,b],Polynomial Integer)
```

Restriction:

Axiom does not allow you to create types where `MultivariatePolynomial` is contained in the coefficient type of `Polynomial`. Therefore, `MPOLY([x,y],POLY INT)` is legal but `POLY MPOLY([x,y],INT)` is not.

Multivariate polynomials may be combined with univariate polynomials to create types with special structures.

```
q : UP(x, FRAC MPOLY([y,z],INT))
      Type: Void
```

This is a polynomial in x whose coefficients are quotients of polynomials in y and z .

$$(7) \quad q := (x^2 - x(z+1)/y + 2)^2$$

$$x^4 + \frac{-2z - 2}{y} x^3 + \frac{4y^2 + z^2 + 2z + 1}{y^2} x^2 + \frac{-4z - 4}{y} x + 4$$

Type: UnivariatePolynomial(x, Fraction MultivariatePolynomial([y,z], Integer))

Use conversions for structural rearrangements. z does not appear in a denominator and so it can be made the main variable.

$$q :: UP(z, FRAC MPOLY([x,y], INT))$$

$$x^2 - 2yx + 2x^2 - 4yx^2 + \frac{y^2 x^4 - 2y^3 x^3 + (4y^2 + 1)x^2 - 4yx + 4y^2}{y^2} z + \frac{y^2 x^4 - 2y^3 x^3 + (4y^2 + 1)x^2 - 4yx + 4y^2}{y^2} z^2$$

Type: UnivariatePolynomial(z, Fraction MultivariatePolynomial([x,y], Integer))

Or you can make a multivariate polynomial in x and z whose coefficients are fractions in polynomials in y .

$$q :: MPOLY([x,z], FRAC UP(y, INT))$$

$$x^4 + (-\frac{z}{y} - \frac{z^2}{y})x^3 + (\frac{1}{y} - \frac{z}{y} + \frac{z^2}{y})x^2 + \frac{4y^2 + 1}{y^2}x + (-\frac{z}{y} - \frac{z^2}{y})x + 4$$

Type: MultivariatePolynomial([x,z], Fraction UnivariatePolynomial(y, Integer))

A conversion like $q :: MPOLY([x,y], FRAC UP(z, INT))$ is not possible in this example because y appears in the denominator of a fraction. As you can see, Axiom provides extraordinary flexibility in the manipulation and display of expressions via its conversion facility.

domain NSMP NewSparseMultivariatePolynomial

Based on the **PseudoRemainderSequence** package, the domain constructor **NewSparseMultivariatePolynomial** extends the constructor **SparseMultivariatePolynomial**. It also provides some additional operations related to polynomial system solving by means of triangular sets.

```
=====
None examples
=====
```

The None domain is not very useful for interactive work but it is provided nevertheless for completeness of the Axiom type system.

Probably the only place you will ever see it is if you enter an empty list with no type information.

```
[ ]
[]
                                         Type: List None
```

Such an empty list can be converted into an empty list of any other type.

```
[ ] :: List Float
[]
                                         Type: List Float
```

If you wish to produce an empty list of a particular type directly, such as List NonNegativeInteger, do it this way.

```
[ ]$List(NonNegativeInteger)
[]
                                         Type: List NonNegativeInteger
```

=====

NottinghamGroup examples

=====

n

If F is a finite field with p elements, then we may form the group of all formal power series $\{t(1+a_1t+a_2t^2+\dots)\}$ where $u(0)=0$ and $u(0)=1$ and a_i is an element of F .

i

The group operation is substitution (composition).
This is called the Nottingham Group.

The Nottingham Group is the projective limit of finite p -groups.
Every finite p -group can be embedded in the Nottingham Group.

NumericalIntegrationProblem examples

=====

NumericalIntegrationProblem is a domain for the representation of
Numerical Integration problems for use by ANNA.

The representation is a Union of two record types - one for integration of
a function of one variable:

```
Record(var:Symbol,
       fn:Expression DoubleFloat,

Chapter 16

Chapter O

domain OCT Octonion

The octonions have the following multiplication table:

1	i	j	k	E	I	J	K
i	-1	k	$-j$	I	$-E$	$-K$	J
j	$-k$	-1	i	J	K	$-E$	$-I$
k	j	$-i$	-1	K	$-J$	I	$-E$
E	$-I$	$-J$	$-K$	-1	i	j	k
I	E	$-K$	J	$-i$	-1	$-k$	j
J	K	E	$-I$	$-j$	k	-1	$-i$
K	$-J$	I	E	$-k$	$-j$	i	-1

There are 3 different kinds of associativity. An algebra is

- **power-associative** if the subalgebra generated by any one element is associative. That is, given any element e then $e * (e * e) = (e * e) * e$.
- **alternative** if the subalgebra generated by any two elements is associative. That is, given any two elements, a and b then $a * (a * b) = (a * a) * b$ and $a * (b * a) = (a * b) * a$ and $b * (a * a) = (b * a) * a$.
- **associative** if the subalgebra generated by any three elements is associative. That is, given any three elements a , b , and c then $a * (b * c) = (a * b) * c$.

The Octonions are power-associative and alternative but not associative, since $I * (J * K) \neq (I * J) * K$.

=====

Octonion examples

=====

The Octonions, also called the Cayley-Dixon algebra, defined over a commutative ring are an eight-dimensional non-associative algebra. Their construction from quaternions is similar to the construction of quaternions from complex numbers.

As Octonion creates an eight-dimensional algebra, you have to give eight components to construct an octonion.

```

oci1 := octon(1,2,3,4,5,6,7,8)
      1 + 2i + 3j + 4k + 5E + 6I + 7J + 8K
                        Type: Octonion Integer

```

```

oci2 := octon(7,2,3,-4,5,6,-7,0)
      7 + 2i + 3j - 4k + 5E + 6I - 7J
                        Type: Octonion Integer

```

Or you can use two quaternions to create an octonion.

```

oci3 := octon(quatern(-7,-12,3,-10), quatern(5,6,9,0))
      - 7 - 12i + 3j - 10k + 5E + 6I + 9J
                        Type: Octonion Integer

```

You can easily demonstrate the non-associativity of multiplication.

```

(oci1 * oci2) * oci3 - oci1 * (oci2 * oci3)
      2696i - 2928j - 4072k + 16E - 1192I + 832J + 2616K
                        Type: Octonion Integer

```

As with the quaternions, we have a real part, the imaginary parts i, j, k, and four additional imaginary parts E, I, J and K. These parts correspond to the canonical basis (1,i,j,k,E,I,J,K).

For each basis element there is a component operation to extract the coefficient of the basis element for a given octonion.

```
[real oci1, imagi oci1, imagj oci1, imagk oci1, _
  imagE oci1, imagI oci1, imagJ oci1, imagK oci1]
[1,2,3,4,5,6,7,8]
```

Type: List PositiveInteger

A basis with respect to the quaternions is given by (1,E). However, you might ask, what then are the commuting rules? To answer this, we create some generic elements.

We do this in Axiom by simply changing the ground ring from Integer to Polynomial Integer.

```
q : Quaternion Polynomial Integer := quatern(q1, qi, qj, qk)
q1 + qi i + qj j + qk k
```

Type: Quaternion Polynomial Integer

```
E : Octonion Polynomial Integer := octon(0,0,0,0,1,0,0,0)
E
```

Type: Octonion Polynomial Integer

Note that quaternions are automatically converted to octonions in the obvious way.

```
q * E
q1 E + qi I + qj J + qk K
```

Type: Octonion Polynomial Integer

```
E * q
q1 E - qi I - qj J - qk K
```

Type: Octonion Polynomial Integer

```
q * 1$(Octonion Polynomial Integer)
q1 + qi i + qj j + qk k
```

Type: Octonion Polynomial Integer

```
1$(Octonion Polynomial Integer) * q
q1 + qi i + qj j + qk k
```

Type: Octonion Polynomial Integer

Finally, we check that the norm, defined as the sum of the squares of the coefficients, is a multiplicative map.

```
o : Octonion Polynomial Integer := octon(o1, oi, oj, ok, oE, oI, oJ, oK)
o1 + oi i + oj j + ok k + oE E + oI I + oJ J + oK K
```

Type: Octonion Polynomial Integer

```
norm o
      2      2      2      2      2      2      2      2
ok  + oj  + oi  + oK  + oJ  + oI  + oE  + o1
```

Type: Polynomial Integer

```
p : Octonion Polynomial Integer := octon(p1, pi, pj, pk, pE, pI, pJ, pK)
p1 + pi i + pj j + pk k + pE E + pI I + pJ J + pK K
Type: Octonion Polynomial Integer
```

Since the result is 0, the norm is multiplicative.

```
norm(o*p)-norm(p)*norm(o)
0
Type: Polynomial Integer
```

=====

OneDimensionalArray examples

=====

The OneDimensionalArray domain is used for storing data in a one-dimensional indexed data structure. Such an array is a homogeneous data structure in that all the entries of the array must belong to the same Axiom domain. Each array has a fixed length specified by the user and arrays are not extensible. The indexing of one-dimensional arrays is one-based. This means that the "first" element of an array is given the index 1.

To create a one-dimensional array, apply the operation `oneDimensionalArray` to a list.

```

oneDimensionalArray [i**2 for i in 1..10]
[1,4,9,16,25,36,49,64,81,100]
Type: OneDimensionalArray PositiveInteger

```

Another approach is to first create `a`, a one-dimensional array of 10 0's. `OneDimensionalArray` has the convenient abbreviation `ARRAY1`.

```

a : ARRAY1 INT := new(10,0)
[0,0,0,0,0,0,0,0,0,0]

```

Type: OneDimensionalArray Integer

Set each i-th element to i, then display the result.

```
for i in 1..10 repeat a.i := i; a
[1,2,3,4,5,6,7,8,9,10]
```

Type: OneDimensionalArray Integer

Square each element by mapping the function $i \mapsto i^2$ onto each element.

```
map!(i ↦ i ** 2,a); a
[1,4,9,16,25,36,49,64,81,100]
```

Type: OneDimensionalArray Integer

Reverse the elements in place.

```
reverse! a
[100,81,64,49,36,25,16,9,4,1]
```

Type: OneDimensionalArray Integer

Swap the 4th and 5th element.

```
swap!(a,4,5); a
[100,81,64,36,49,25,16,9,4,1]
```

Type: OneDimensionalArray Integer

Sort the elements in place.

```
sort! a
[1,4,9,16,25,36,49,64,81,100]
```

Type: OneDimensionalArray Integer

Create a new one-dimensional array b containing the last 5 elements of a.

```
b := a(6..10)
[36,49,64,81,100]
```

Type: OneDimensionalArray Integer

Replace the first 5 elements of a with those of b.

```
copyInto!(a,b,1)
[36,49,64,81,100,36,49,64,81,100]
```

Type: OneDimensionalArray Integer

=====

Operator examples

=====

Given any ring R, the ring of the Integer-linear operators over R is called `Operator(R)`. To create an operator over R, first create a basic operator using the operation operator, and then convert it to `Operator(R)` for the R you want.

We choose R to be the two by two matrices over the integers.

```

R := SQMATRIX(2, INT)
   SquareMatrix(2,Integer)
                                     Type: Domain

```

Create the operator tilde on R.

```

t := operator("tilde") :: OP(R)
   tilde
                                     Type: Operator SquareMatrix(2,Integer)

```

Since `Operator` is unexposed we must either package-call operations from it, or expose it explicitly. For convenience we will do the latter.

Expose `Operator`.

```

)set expose add constructor Operator

```

To attach an evaluation function (from R to R) to an operator over R, use `evaluate(op, f)` where `op` is an operator over R and `f` is a function `R -> R`. This needs to be done only once when the operator is defined. Note that `f` must be Integer-linear (that is, $f(ax+y) = a f(x) + f(y)$ for any integer `a`, and any `x` and `y` in R).

```
evaluate(t, m +> transpose m)
tilde
```

Type: Operator SquareMatrix(2,Integer)

```
s : R := matrix [ [0, 1], [1, 0] ]  
+0  1+  
|    |  
+1  0+
```

Type: SquareMatrix(2,Integer)

```

rho := t * s
      +0 1+
      tilde| |
      +1 0+
Type: Operator SquareMatrix(2,Integer)

```

```

z := rho**4 - 1
      +0 1+      +0 1+      +0 1+      +0 1+
- 1 + tilde| |tilde| |tilde| |tilde| |
      +1 0+      +1 0+      +1 0+      +1 0+
Type: Operator SquareMatrix(2,Integer)

```

```
m:=R := matrix [ [1, 2], [3, 4] ]  
      +1  2+  
      |   |  
      +3  4+  
  
Type: SquareMatrix(2,Integer)
```

```

z m
+0  0+
|    |
+0  0+

Type: SquareMatrix(2,Integer)

```

As you have probably guessed by now, ρ acts on matrices by rotating the elements clockwise.

```
rho m
  +3  1+
  |   |
  +4  2+
                                     Type: SquareMatrix(2,Integer)
```

```
rho rho m
  +4  3+
  |   |
  +2  1+
                                     Type: SquareMatrix(2,Integer)
```

```
(rho^3) m
  +2  4+
  |   |
  +1  3+
                                     Type: SquareMatrix(2,Integer)
```

Do the swapping of rows and transposition commute? We can check by computing their bracket.

```
b := t * s - s * t
      +0  1+          +0  1+
      - |   |tilde + tilde|   |
      +1  0+          +1  0+
                                     Type: Operator SquareMatrix(2,Integer)
```

Now apply it to m .

```
b m
  +1  - 3+
  |       |
  +3  - 1+
                                     Type: SquareMatrix(2,Integer)
```

Next we demonstrate how to define a differential operator on a polynomial ring.

This is the recursive definition of the n -th Legendre polynomial.

```
L n ==
  n = 0 => 1
  n = 1 => x
  (2*n-1)/n * x * L(n-1) - (n-1)/n * L(n-2)
                                     Type: Void
```

Create the differential operator d/dx on polynomials in x over the

rational numbers.

```
dx := operator("D") :: OP(POLY FRAC INT)
D
Type: Operator Polynomial Fraction Integer
```

Now attach the map to it.

```
evaluate(dx, p +-> D(p, 'x))
D
Type: Operator Polynomial Fraction Integer
```

This is the differential equation satisfied by the n-th Legendre polynomial.

```
E n == (1 - x**2) * dx**2 - 2 * x * dx + n*(n+1)
Type: Void
```

Now we verify this for n = 15. Here is the polynomial.

```
L 15
 9694845 15 35102025 13 50702925 11 37182145 9 14549535 7
----- x - ----- x + ----- x - ----- x + ----- x
 2048      2048      2048      2048      2048
+
 2909907 5 255255 3 6435
- ----- x + ----- x - ----- x
 2048      2048      2048
Type: Polynomial Fraction Integer
```

Here is the operator.

```
E 15
240 - 2x D - (x - 1)D
Type: Operator Polynomial Fraction Integer
```

Here is the evaluation.

```
(E 15)(L 15)
0
Type: Polynomial Fraction Integer
```

OrderedDirectProduct examples
=====

```

This type represents the finite direct or cartesian product of an underlying ordered component type. The ordering on the type is determined

by its third argument which represents the less than function on vectors. This type is a suitable third argument for `GeneralDistributedMultivariatePolynomial`.

=====
OrderedFreeMonoid examples
=====
```

The free monoid on a set S is the monoid of finite products of the form $\text{reduce}(*, [s_i ** n_i])$ where the s_i 's are in S , and the n_i 's are non-negative integers. The multiplication is not commutative. For two elements x and y the relation $x < y$ holds if either $\text{length}(x) < \text{length}(y)$ holds or if these lengths are equal and if x is smaller than y w.r.t. the lexicographical ordering induced by S . This domain inherits implementation from `FreeMonoid`.

```
m1:=(x*y*y*z)$OFMONOID(Symbol)
```

```
m2:=(x*y)$OFMONOID(Symbol)
```

```
lquo(m1,m2)
```

```
m3:=(y*y)$OFMONOID(Symbol)
```

```
div(m1,m2)
```

```
div(m1,m3)
```

```
m4:=(y^3)$OFMONOID(Symbol)
```

```
div(m1,m4)
```

Build the non-commutative algebra $h=k[x,y]$ and then make computations in h using some predefined rules for x and y . For example, giving

```
x*y*x=y*x*y
x*x=a*x+b
y*y=a*y+b
```

where a and b are generic elements of k .

Then reduce the polynomials in x and y according to the previous rules. That is, given

```
(x+y)^2  ( = x^2+x*y+y*x+y^2)
```

should reduce to

```
a*(x+y)+2*b+x*y+y*x
```

We can reduce the clutter of the work by defining macros for the types of the domains we need to create. So first we create those macros.

We create generic elements of k . First we define a macro for the domain of ordered variables (OVAR is OrderedVariableList)

```
C ==> OVAR [a,b]
```

Next we define a macro for the commutative field domain $k = \mathbb{Q}[a,b]$ where \mathbb{Q} is Fraction(Integer) and SMP is SparseMultivariatePolynomials

```
K ==> SMP(FRAC INT,C)
```

Now we need some non-commutative variables so we create a macro for that.

```
V ==> OVAR [x,y]
```

And now we need to define the non-commutative algebra $k=k[x,y]$. We use the domain XDistributedPolynomial (XDPOLY) as a macro.

```
H ==> XDPOLY(V,K)
```

The non-commutative variables are in an Ordered Free Monoid

```
M ==> OFMONOID V
```

We have three rules to apply. So we create a function that examines one term. Substitution rules are applied to words from the monoid over the variables and return polynomials. If any rule matches we construct the substitution, create a new monomial term and return it.

```
subs(w:M):H ==
  -- x*y*x = y*x*y
  n1:=lquo(w,(x::V*y::V*x::V)$M)$M
  n1 case "failed" => monom(w,1)$H
    -- x*x = a*x+b
    n2:=lquo(w,(x::V^2)$M)$M
    n2 case "failed" => monom(w,1)$H
      -- y*y = a*y+b
      n3:=lquo(w,(y::V^2)$M)$M
      n3 case "failed" => monom(w,1)$H
        monom(n3,1)$H * (a::K*y::V+b::K)$M * monom(n3,1)$H
        monom(n2,1)$H * (a::K*x::V+b::K)$H * monom(n2,1)$H
        monom(n1,1)$H * (y::V*x::V*y::V)$H * monom(n1,1)$H
```

We apply these rules to a term, remembering the coefficient

```
newterm(x:Record(k:M,c:K)):H == x.c*subs(x,k)
```

And now we create a function to reconstruct the polynomial term by term.

```
newpoly(t:H):H == reduce(+,map(newterm,listOfTerms(t)))
```

For example,

```
p1:(x::V+y::V)$H^2
newpoly(p1)
p2:=(x::V+y::V)$H^3
pNew:=newpoly(p2)
```

But the rules should be applied more than once so we create a function to iterate the rules until nothing changes.

```
reduce(p:H):H ==
  p2 := newpoly(p)
  p3 := newpoly(p2)
  while p3 ~= p2 repeat
    p2 := p3
    p3 := newpoly(p2)
  p3
```

And we can see it work

```
reduce(p2)
```

=====

OrderedVariableList examples

=====

The domain OrderedVariableList provides symbols which are restricted to a particular list and have a definite ordering. Those two features are specified by a List Symbol object that is the argument to the domain.

This is a sample ordering of three symbols.

```

ls:List Symbol:=['x','a','z']
    [x,a,z]
                                     Type: List Symbol

```

Let's build the domain

```

Z:=OVAR ls
    OrderedVariableList [x,a,z]
                                     Type: Domain

```

How many variables does it have?

```

size()$Z

```

```
3
```

```
Type: NonNegativeInteger
```

They are (in the imposed order)

```
lv:=[index(i::PI)$Z for i in 1..size()$Z]
[x,a,z]
```

```
Type: List OrderedVariableList [x,a,z]
```

Check that the ordering is right

```
sorted?(>,lv)
true
```

```
Type: Boolean
```

=====
OrderlyDifferentialPolynomial examples
=====

```

Many systems of differential equations may be transformed to equivalent systems of ordinary differential equations where the equations are expressed polynomially in terms of the unknown functions. In Axiom, the domain constructors `OrderlyDifferentialPolynomial` (abbreviated `ODPOL`) and `SequentialDifferentialPolynomial` (abbreviation `SDPOL`) implement two domains of ordinary differential polynomials over any differential ring. In the simplest case, this differential ring is usually either the ring of integers, or the field of rational numbers. However, Axiom can handle ordinary differential polynomials over a field of rational functions in a single indeterminate.

The two domains `ODPOL` and `SDPOL` are almost identical, the only difference being the choice of a different ranking, which is an ordering of the derivatives of the indeterminates. The first domain uses an orderly ranking, that is, derivatives of higher order are ranked higher, and derivatives of the same order are ranked alphabetically. The second domain uses a sequential ranking, where derivatives are ordered first alphabetically by the differential indeterminates, and then by order. A more general domain constructor, `DifferentialSparseMultivariatePolynomial` (abbreviation `DSMP`) allows both a user-provided list of differential indeterminates as well as a user-defined ranking. We shall illustrate `ODPOL(FRAC INT)`, which constructs a domain of ordinary differential polynomials in an arbitrary number of differential indeterminates with rational numbers as coefficients.

```
dpol:= ODPOL(FRAC INT)
      OrderlyDifferentialPolynomial Fraction Integer
      Type: Domain
```

A differential indeterminate `w` may be viewed as an infinite sequence of algebraic indeterminates, which are the derivatives of `w`. To facilitate referencing these, Axiom provides the operation `makeVariable` to convert an element of type `Symbol` to a map from the natural numbers to the differential polynomial ring.

```
w := makeVariable('w)$dpol
      theMap(DPOLCAT-;makeVariable;AM;17!0,0)
Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)

z := makeVariable('z)$dpol
      theMap(DPOLCAT-;makeVariable;AM;17!0,0)
Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)
```

The fifth derivative of `w` can be obtained by applying the map `w` to the number 5. Note that the order of differentiation is given as a subscript (except when the order is 0).

```
w.5
w
5
```

Type: OrderlyDifferentialPolynomial Fraction Integer

w 0
w

Type: OrderlyDifferentialPolynomial Fraction Integer

The first five derivatives of z can be generated by a list.

[z.i for i in 1..5]
[z ,z ,z ,z ,z]
1 2 3 4 5

Type: List OrderlyDifferentialPolynomial Fraction Integer

The usual arithmetic can be used to form a differential polynomial from the derivatives.

f:= w.4 - w.1 * w.1 * z.3
2
w - w z
4 1 3

Type: OrderlyDifferentialPolynomial Fraction Integer

g:=(z.1)**3 * (z.2)**2 - w.2
3 2
z z - w
1 2 2

Type: OrderlyDifferentialPolynomial Fraction Integer

The operation D computes the derivative of any differential polynomial.

D(f)
2
w - w z - 2w w z
5 1 4 1 2 3

Type: OrderlyDifferentialPolynomial Fraction Integer

The same operation can compute higher derivatives, like the fourth derivative.

D(f,4)
2 2
w - w z - 8w w z + (- 12w w - 12w)z - 2w z w
8 1 7 1 2 6 1 3 2 5 1 3 5
+
2
(- 8w w - 24w w)z - 8w z w - 6w z
1 4 2 3 4 2 3 4 3 3

Type: OrderlyDifferentialPolynomial Fraction Integer

The operation makeVariable creates a map to facilitate referencing the derivatives of f, similar to the map w.

```
df:=makeVariable(f)$dpol
  theMap(DPOLCAT-;makeVariable;AM;17!0,0)
Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)
```

The fourth derivative of f may be referenced easily.

```
df.4
      2
      w  - w  z  - 8w w z  + (- 12w w  - 12w  )z  - 2w z w
      8    1  7    1 2 6    1 3    2    5    1 3 5
+
      2
      (- 8w w  - 24w w )z  - 8w z w  - 6w  z
      1 4    2 3 4    2 3 4    3 3
Type: OrderlyDifferentialPolynomial Fraction Integer
```

The operation order returns the order of a differential polynomial, or the order in a specified differential indeterminate.

```
order(g)
2
Type: PositiveInteger
```

```
order(g, 'w)
2
Type: PositiveInteger
```

The operation differentialVariables returns a list of differential indeterminates occurring in a differential polynomial.

```
differentialVariables(g)
[z,w]
Type: List Symbol
```

The operation degree returns the degree, or the degree in the differential indeterminate specified.

```
degree(g)
  2 3
  z z
  2 1
Type: IndexedExponents OrderlyDifferentialVariable Symbol
```

```
degree(g, 'w)
1
Type: PositiveInteger
```

The operation weights returns a list of weights of differential monomials appearing in differential polynomial, or a list of weights in a specified

differential indeterminate.

```
weights(g)
[7,2]
Type: List NonNegativeInteger
```

```
weights(g,'w')
[2]
Type: List NonNegativeInteger
```

The operation `weight` returns the maximum weight of all differential monomials appearing in the differential polynomial.

```
weight(g)
7
Type: PositiveInteger
```

A differential polynomial is isobaric if the weights of all differential monomials appearing in it are equal.

```
isobaric?(g)
false
Type: Boolean
```

To substitute differentially, use `eval`. Note that we must coerce `'w` to `Symbol`, since in `ODPOL`, differential indeterminates belong to the domain `Symbol`. Compare this result to the next, which substitutes algebraically (no substitution is done since `w.0` does not appear in `g`).

```
eval(g,['w::Symbol],[f])
      2          2          3 2
- w + w z + 4w w z + (2w w + 2w )z + z z
  6   1 5   1 2 4   1 3   2 3   1 2
Type: OrderlyDifferentialPolynomial Fraction Integer
```

```
eval(g,variables(w.0),[f])
      3 2
z z - w
1 2   2
Type: OrderlyDifferentialPolynomial Fraction Integer
```

Since `OrderlyDifferentialPolynomial` belongs to `PolynomialCategory`, all the operations defined in the latter category, or in packages for the latter category, are available.

```
monomials(g)
      3 2
[z z , - w ]
  1 2   2
Type: List OrderlyDifferentialPolynomial Fraction Integer
```

```

variables(g)
  [z ,w ,z ]
    2 2 1
Type: List OrderlyDifferentialVariable Symbol

gcd(f,g)
  1
Type: OrderlyDifferentialPolynomial Fraction Integer

groebner([f,g])
      2      3 2
[w - w z ,z z - w ]
  4      1 3 1 2      2
Type: List OrderlyDifferentialPolynomial Fraction Integer

```

The next three operations are essential for elimination procedures in differential polynomial rings. The operation leader returns the leader of a differential polynomial, which is the highest ranked derivative of the differential indeterminates that occurs.

```

lg:=leader(g)
  z
  2
Type: OrderlyDifferentialVariable Symbol

```

The operation separant returns the separant of a differential polynomial, which is the partial derivative with respect to the leader.

```

sg:=separant(g)
  3
  2z z
  1 2
Type: OrderlyDifferentialPolynomial Fraction Integer

```

The operation initial returns the initial, which is the leading coefficient when the given differential polynomial is expressed as a polynomial in the leader.

```

ig:=initial(g)
  3
  z
  1
Type: OrderlyDifferentialPolynomial Fraction Integer

```

Using these three operations, it is possible to reduce f modulo the differential ideal generated by g . The general scheme is to first reduce the order, then reduce the degree in the leader. First, eliminate $z.3$ using the derivative of g .

```

g1 := D g
      3          2 3
    2z z z - w + 3z z
      1 2 3      1 2
Type: OrderlyDifferentialPolynomial Fraction Integer

```

Find its leader.

```

lg1:= leader g1
      z
      3
Type: OrderlyDifferentialVariable Symbol

```

Differentiate f partially with respect to this leader.

```

pdf:=D(f, lg1)
      2
    - w
      1
Type: OrderlyDifferentialPolynomial Fraction Integer

```

Compute the partial remainder of f with respect to g.

```

prf:=sg * f- pdf * g1
      3          2          2 2 3
    2z z w - w w + 3w z z
      1 2 4      1 3      1 1 2
Type: OrderlyDifferentialPolynomial Fraction Integer

```

Note that high powers of lg still appear in prf. Compute the leading coefficient of prf as a polynomial in the leader of g.

```

lcf:=leadingCoefficient univariate(prf, lg)
      2 2
    3w z
      1 1
Type: OrderlyDifferentialPolynomial Fraction Integer

```

Finally, continue eliminating the high powers of lg appearing in prf to obtain the (pseudo) remainder of f modulo g and its derivatives.

```

ig * prf - lcf * g * lg
      6          2 3          2 2
    2z z w - w z w + 3w z w z
      1 2 4      1 1 3      1 1 2 2
Type: OrderlyDifferentialPolynomial Fraction Integer

```

— domain ODPOL OrderlyDifferentialPolynomial —

```

)abbrev domain ODPOL OrderlyDifferentialPolynomial
++ Author: William Sit
++ Date Created: 24 September, 1991
++ Date Last Updated: 7 February, 1992
++ References: Kolchin, E.R. "Differential Algebra and Algebraic Groups"
++ (Academic Press, 1973).
++ Description:
++ \spadtype{OrderlyDifferentialPolynomial} implements
++ an ordinary differential polynomial ring in arbitrary number
++ of differential indeterminates, with coefficients in a
++ ring. The ranking on the differential indeterminate is orderly.
++ This is analogous to the domain \spadtype{Polynomial}.

```

=====
OrderlyDifferentialVariable examples
=====

```

OrderlyDifferentialVariable adds a commonly used orderly ranking to the set of derivatives of an ordered list of differential indeterminates. An orderly ranking is a ranking $<$ of the derivatives with the property that for two derivatives u and v , $u < v$ if the order of u is less than that of v .

This domain belongs to DifferentialVariableCategory. It defines weight to be just order, and it defines an orderly ranking $<$ on derivatives u via the lexicographic order on the pair $(\text{order}(u), \text{variable}(u))$.

)abbrev domain OUTFORM OutputForm
++ Author: SMW March/88
++ Description:
++ This domain is used to create and manipulate mathematical expressions
++ for output. It is intended to provide an insulating layer between
++ the expression rendering software (e.g.FORTRAN, TeX, or Script) and
++ the output coercions in the various domains.

OutputForm(): SetCategory with
  --% Printing
  print : $ -> Void
    ++ print(u) prints the form u.
  message: String -> $
    ++ message(s) creates an form with no string quotes
    ++ from string s.
  messagePrint: String -> Void
    ++ messagePrint(s) prints s without string quotes. Note:
    ++ \spad{messagePrint(s)} is equivalent to \spad{print message(s)}.
  --% Creation of atomic forms
  outputForm: Integer -> $
    ++ outputForm(n) creates an form for integer n.
  outputForm: Symbol -> $
    ++ outputForm(s) creates an form for symbol s.
  outputForm: String -> $
    ++ outputForm(s) creates an form for string s.
  outputForm: DoubleFloat -> $
    ++ outputForm(sf) creates an form for small float sf.
  empty : () -> $
    ++ empty() creates an empty form.

```

```

--% Sizings
width: $ -> Integer
    ++ width(f) returns the width of form f (an integer).
height: $ -> Integer
    ++ height(f) returns the height of form f (an integer).
width: -> Integer
    ++ width() returns the width of the display area (an integer).
height: -> Integer
    ++ height() returns the height of the display area (an integer).
subHeight: $ -> Integer
    ++ subHeight(f) returns the height of form f below the base line.
superHeight: $ -> Integer
    ++ superHeight(f) returns the height of form f above the base line.
--% Space manipulations
hspace: Integer -> $ ++ hspace(n) creates white space of width n.
vspace: Integer -> $ ++ vspace(n) creates white space of height n.
rspace: (Integer,Integer) -> $
    ++ rspace(n,m) creates rectangular white space, n wide by m high.
--% Area adjustments
left: ($,Integer) -> $
    ++ left(f,n) left-justifies form f within space of width n.
right: ($,Integer) -> $
    ++ right(f,n) right-justifies form f within space of width n.
center: ($,Integer) -> $
    ++ center(f,n) centers form f within space of width n.
left: $ -> $
    ++ left(f) left-justifies form f in total space.
right: $ -> $
    ++ right(f) right-justifies form f in total space.
center: $ -> $
    ++ center(f) centers form f in total space.

--% Area manipulations
hconcat: ($,$) -> $
    ++ hconcat(f,g) horizontally concatenate forms f and g.
vconcat: ($,$) -> $
    ++ vconcat(f,g) vertically concatenates forms f and g.
hconcat: List $ -> $
    ++ hconcat(u) horizontally concatenates all forms in list u.
vconcat: List $ -> $
    ++ vconcat(u) vertically concatenates all forms in list u.

--% Application formers
prefix: ($, List $) -> $
    ++ prefix(f,l) creates a form depicting the n-ary prefix
    ++ application of f to a tuple of arguments given by list l.
infix: ($, List $) -> $
    ++ infix(f,l) creates a form depicting the n-ary application
    ++ of infix operation f to a tuple of arguments l.
infix: ($, $, $) -> $

```

```

++ infix(op, a, b) creates a form which prints as: a op b.
postfix: ($, $) -> $
++ postfix(op, a) creates a form which prints as: a op.
infix?: $ -> Boolean
++ infix?(op) returns true if op is an infix operator,
++ and false otherwise.
elt: ($, List $) -> $
++ elt(op,l) creates a form for application of op
++ to list of arguments l.

--% Special forms
string: $ -> $
++ string(f) creates f with string quotes.
label: ($, $) -> $
++ label(n,f) gives form f an equation label n.
box: $ -> $
++ box(f) encloses f in a box.
matrix: List List $ -> $
++ matrix(llf) makes llf (a list of lists of forms) into
++ a form which displays as a matrix.
zag: ($, $) -> $
++ zag(f,g) creates a form for the continued fraction form for f over g.
root: $ -> $
++ root(f) creates a form for the square root of form f.
root: ($, $) -> $
++ root(f,n) creates a form for the nth root of form f.
over: ($, $) -> $
++ over(f,g) creates a form for the vertical fraction of f over g.
slash: ($, $) -> $
++ slash(f,g) creates a form for the horizontal fraction of f over g.
assign: ($, $) -> $
++ assign(f,g) creates a form for the assignment \spad{f := g}.
rarrow: ($, $) -> $
++ rarrow(f,g) creates a form for the mapping \spad{f -> g}.
differentiate: ($, NonNegativeInteger) -> $
++ differentiate(f,n) creates a form for the nth derivative of f,
++ e.g. \spad{f'}, \spad{f''}, \spad{f'''},
++ "f super \spad{iv}".
binomial: ($, $) -> $
++ binomial(n,m) creates a form for the binomial coefficient of n and m.

--% Scripts
sub: ($, $) -> $
++ sub(f,n) creates a form for f subscripted by n.
super: ($, $) -> $
++ super(f,n) creates a form for f superscripted by n.
presub: ($, $) -> $
++ presub(f,n) creates a form for f presubscripted by n.
presuper: ($, $) -> $
++ presuper(f,n) creates a form for f presuperscripted by n.

```

```

scripts: ($, List $) -> $
  ++ \spad{scripts}(f, [sub, super, presuper, presub])}
  ++ creates a form for f with scripts on all 4 corners.
supersub: ($, List $) -> $
  ++ supersub(a, [sub1,super1,sub2,super2,...])
  ++ creates a form with each subscript aligned
  ++ under each superscript.

--% Diacritical marks
quote: $ -> $
  ++ quote(f) creates the form f with a prefix quote.
dot: $ -> $
  ++ dot(f) creates the form with a one dot overhead.
dot: ($, NonNegativeInteger) -> $
  ++ dot(f,n) creates the form f with n dots overhead.
prime: $ -> $
  ++ prime(f) creates the form f followed by a suffix prime (single quote).
prime: ($, NonNegativeInteger) -> $
  ++ prime(f,n) creates the form f followed by n primes.
overbar: $ -> $
  ++ overbar(f) creates the form f with an overbar.
overlabel: ($, $) -> $
  ++ overlabel(x,f) creates the form f with "x overbar" over the top.

--% Plexes
sum: ($) -> $
  ++ sum(expr) creates the form prefixing expr by a capital sigma.
sum: ($, $) -> $
  ++ sum(expr,lowerlimit) creates the form prefixing expr by
  ++ a capital sigma with a lowerlimit.
sum: ($, $, $) -> $
  ++ sum(expr,lowerlimit,upperlimit) creates the form prefixing expr by
  ++ a capital sigma with both a lowerlimit and upperlimit.
prod: ($) -> $
  ++ prod(expr) creates the form prefixing expr by a capital pi.
prod: ($, $) -> $
  ++ prod(expr,lowerlimit) creates the form prefixing expr by
  ++ a capital pi with a lowerlimit.
prod: ($, $, $) -> $
  ++ prod(expr,lowerlimit,upperlimit) creates the form prefixing expr by
  ++ a capital pi with both a lowerlimit and upperlimit.
int: ($) -> $
  ++ int(expr) creates the form prefixing expr with an integral sign.
int: ($, $) -> $
  ++ int(expr,lowerlimit) creates the form prefixing expr by an
  ++ integral sign with a lowerlimit.
int: ($, $, $) -> $
  ++ int(expr,lowerlimit,upperlimit) creates the form prefixing expr by
  ++ an integral sign with both a lowerlimit and upperlimit.

```

```

--% Matchfix forms
brace:  $ -> $
  ++ brace(f) creates the form enclosing f in braces (curly brackets).
brace:  List $ -> $
  ++ brace(lf) creates the form separating the elements of lf
  ++ by commas and encloses the result in curly brackets.
bracket: $ -> $
  ++ bracket(f) creates the form enclosing f in square brackets.
bracket: List $ -> $
  ++ bracket(lf) creates the form separating the elements of lf
  ++ by commas and encloses the result in square brackets.
paren:  $ -> $
  ++ paren(f) creates the form enclosing f in parentheses.
paren:  List $ -> $
  ++ paren(lf) creates the form separating the elements of lf
  ++ by commas and encloses the result in parentheses.

--% Separators for aggregates
pile:   List $ -> $
  ++ pile(l) creates the form consisting of the elements of l which
  ++ displays as a pile, i.e. the elements begin on a new line and
  ++ are indented right to the same margin.

commaSeparate: List $ -> $
  ++ commaSeparate(l) creates the form separating the elements of l
  ++ by commas.
semicolonSeparate: List $ -> $
  ++ semicolonSeparate(l) creates the form separating the elements of l
  ++ by semicolons.
blankSeparate: List $ -> $
  ++ blankSeparate(l) creates the form separating the elements of l
  ++ by blanks.

--% Specific applications
"=":    ($, $) -> $
  ++ f = g creates the equivalent infix form.
"^=":   ($, $) -> $
  ++ f ^= g creates the equivalent infix form.
"<":    ($, $) -> $
  ++ f < g creates the equivalent infix form.
">":    ($, $) -> $
  ++ f > g creates the equivalent infix form.
"<=":   ($, $) -> $
  ++ f <= g creates the equivalent infix form.
">=":   ($, $) -> $
  ++ f >= g creates the equivalent infix form.
"+":    ($, $) -> $
  ++ f + g creates the equivalent infix form.
"-":    ($, $) -> $
  ++ f - g creates the equivalent infix form.
"_-":   ($)    -> $

```

```

    ++ - f creates the equivalent prefix form.
    "*":    ($, $) -> $
    ++ f * g creates the equivalent infix form.
    "/":    ($, $) -> $
    ++ f / g creates the equivalent infix form.
    "**":    ($, $) -> $
    ++ f ** g creates the equivalent infix form.
    "div":   ($, $) -> $
    ++ f div g creates the equivalent infix form.
    "rem":   ($, $) -> $
    ++ f rem g creates the equivalent infix form.
    "quo":   ($, $) -> $
    ++ f quo g creates the equivalent infix form.
    "exquo": ($, $) -> $
    ++ exquo(f,g) creates the equivalent infix form.
    "and":   ($, $) -> $
    ++ f and g creates the equivalent infix form.
    "or":    ($, $) -> $
    ++ f or g creates the equivalent infix form.
    "not":   ($)   -> $
    ++ not f creates the equivalent prefix form.
    SEGMENT: ($,$) -> $
    ++ SEGMENT(x,y) creates the infix form: \spad{x..y}.
    SEGMENT: ($)   -> $
    ++ SEGMENT(x) creates the prefix form: \spad{x..}.

— domain PADICRC PAdicRationalConstructor —

```

)abbrev domain PADICRC PAdicRationalConstructor
++ Author: Clifton J. Williamson
++ Date Created: 10 May 1990
++ Date Last Updated: 10 May 1990
++ Description:
++ This is the category of stream-based representations of Qp.

PAdicRationalConstructor(p,PADIC): Exports == Implementation where
p      : Integer
PADIC  : PAdicIntegerCategory p
CF     ==> ContinuedFraction
I      ==> Integer
NNI    ==> NonNegativeInteger
OUT    ==> OutputForm
L      ==> List
RN     ==> Fraction Integer
ST     ==> Stream

```

```

Exports ==> QuotientFieldCategory(PADIC) with
  approximate: (% , I) -> RN
    ++ \spad{approximate(x,n)} returns a rational number y such that
    ++ \spad{y = x (mod p^n)}.
  continuedFraction: % -> CF RN
    ++ \spad{continuedFraction(x)} converts the p-adic rational number x
    ++ to a continued fraction.
  removeZeroes: % -> %
    ++ \spad{removeZeroes(x)} removes leading zeroes from the
    ++ representation of the p-adic rational \spad{x}.
    ++ A p-adic rational is represented by (1) an exponent and
    ++ (2) a p-adic integer which may have leading zero digits.
    ++ When the p-adic integer has a leading zero digit, a 'leading zero'
    ++ is removed from the p-adic rational as follows:
    ++ the number is rewritten by increasing the exponent by 1 and
    ++ dividing the p-adic integer by p.
    ++ Note: \spad{removeZeroes(f)} removes all leading zeroes from f.
  removeZeroes: (I,% ) -> %
    ++ \spad{removeZeroes(n,x)} removes up to n leading zeroes from
    ++ the p-adic rational \spad{x}.

++ Description:
++ This domain describes four groups of color shades (palettes).

```

```

Palette(): Exports == Implementation where
I      ==> Integer
C      ==> Color
SHADE  ==> ["Dark","Dim","Bright","Pastel","Light"]

```

```

Exports ==> SetCategory with
dark   : C -> %
  ++ dark(c) sets the shade of the indicated hue of c to it's lowest value.
dim    : C -> %
  ++ dim(c) sets the shade of a hue, c,  above dark, but below bright.
bright : C -> %
  ++ bright(c) sets the shade of a hue, c, above dim, but below pastel.
pastel : C -> %
  ++ pastel(c) sets the shade of a hue, c,  above bright, but below light.
light  : C -> %
  ++ light(c) sets the shade of a hue, c,  to it's highest value.
hue    : % -> C
  ++ hue(p) returns the hue field of the indicated palette p.
shade  : % -> I
  ++ shade(p) returns the shade index of the indicated palette p.
coerce : C -> %
  ++ coerce(c) sets the average shade for the palette to that of the
  ++ indicated color c.

```

```

Implementation ==> add
Rep := Record(shadeField:I, hueField:C)

dark   c == [1,c]
dim    c == [2,c]
bright c == [3,c]
pastel c == [4,c]
light  c == [5,c]
hue    p == p.hueField
shade  p == p.shadeField

=====
PartialFraction examples
=====

A partial fraction is a decomposition of a quotient into a sum of quotients where the denominators of the summands are powers of primes. Most people first encounter partial fractions when they are learning integral calculus. For a technical discussion of partial fractions, see, for example, Lang's Algebra. For example, the rational number $1/6$ is decomposed into $1/2-1/3$. You can compute partial fractions of quotients of objects from domains belonging to the category `EuclideanDomain`. For example, `Integer`, `Complex Integer`, and `UnivariatePolynomial(x, Fraction Integer)` all belong to `EuclideanDomain`. In the examples following, we demonstrate how to decompose quotients of each of these kinds of object into partial fractions.

It is necessary that we know how to factor the denominator when we want to compute a partial fraction. Although the interpreter can often do this automatically, it may be necessary for you to include a call to `factor`. In these examples, it is not necessary to factor the denominators explicitly.

The main operation for computing partial fractions is called `partialFraction` and we use this to compute a decomposition of $1/10!$. The first argument to `partialFraction` is the numerator of the quotient and the second argument is the factored denominator.

```

partialFraction(1,factorial 10)
159   23   12   1
--- - -- - -- + -

```

$$\frac{2^8}{2} + \frac{3^4}{3} + \frac{5^2}{5} + \frac{7}{7}$$

Type: PartialFraction Integer

Since the denominators are powers of primes, it may be possible to expand the numerators further with respect to those primes. Use the operation `padicFraction` to do this.

```
f := padicFraction(%)
```

$$-\frac{1}{2} + \frac{1}{2^4} + \frac{1}{2^5} + \frac{1}{2^6} + \frac{1}{2^7} + \frac{1}{2^8} - \frac{2}{2^2} - \frac{1}{2^3} - \frac{2}{2^4} - \frac{2}{2^5} - \frac{2}{2^6} + \frac{1}{2^7}$$

Type: PartialFraction Integer

The operation `compactFraction` returns an expanded fraction into the usual form. The compacted version is used internally for computational efficiency.

```
compactFraction(f)
```

$$-\frac{159}{2} - \frac{23}{3} - \frac{12}{5} + \frac{1}{7}$$

Type: PartialFraction Integer

You can add, subtract, multiply and divide partial fractions. In addition, you can extract the parts of the decomposition. `numberOfFractionalTerms` computes the number of terms in the fractional part. This does not include the whole part of the fraction, which you get by calling `wholePart`. In this example, the whole part is just 0.

```
numberOfFractionalTerms(f)
```

12

Type: PositiveInteger

The operation `nthFractionalTerm` returns the individual terms in the decomposition. Notice that the object returned is a partial fraction itself. `firstNumerator` and `firstDenominator` extract the numerator and denominator of the first term of the fraction.

```
nthFractionalTerm(f,3)
```

$$-\frac{1}{2^5}$$

Type: PartialFraction Integer

Given two gaussian integers, you can decompose their quotient into a partial fraction.

```
partialFraction(1,- 13 + 14 * %i)
      1      4
    - ---- + ----
      1 + 2%i  3 + 8%i
Type: PartialFraction Complex Integer
```

To convert back to a quotient, simply use a conversion.

```
% :: Fraction Complex Integer
      %i
    - ----
      14 + 13%i
Type: Fraction Complex Integer
```

To conclude this section, we compute the decomposition of

$$\frac{1}{(x+1)(x+2)^2(x+3)^3(x+4)^4}$$

The polynomials in this object have type
UnivariatePolynomial(x, Fraction Integer).

We use the primeFactor operation to create the denominator in factored form directly.

```
u : FR UP(x, FRAC INT) := reduce(*,[primeFactor(x+i,i) for i in 1..4])
      2      3      4
    (x + 1)(x + 2) (x + 3) (x + 4)
Type: Factored UnivariatePolynomial(x,Fraction Integer)
```

These are the compact and expanded partial fractions for the quotient.

```
partialFraction(1,u)
      1      1      7      17 2      139 607 3      10115 2      391      44179
    --- - x + -- - -- x - 12x - --- --- x + ---- x + --- x + ----
    648 4      16      8      8      324      432      4      324
    ---- + ---- + ---- + ----
    x + 1      2      3      4
      (x + 2)      (x + 3)      (x + 4)
Type: PartialFraction UnivariatePolynomial(x,Fraction Integer)

padicFraction %

— domain PFR PartialFraction —

```

)abbrev domain PFR PartialFraction
++ Author: Robert S. Sutor
++ Date Created: 1986
++ Change History: 05/20/91 BMT Converted to the new library
++ Description:
++ The domain \spadtype{PartialFraction} implements partial fractions
++ over a euclidean domain \spad{R}. This requirement on the
++ argument domain allows us to normalize the fractions. Of
++ particular interest are the 2 forms for these fractions. The
++ ‘compact’ form has only one fractional term per prime in the
++ denominator, while the ‘p-adic’ form expands each numerator
++ p-adically via the prime p in the denominator. For computational
++ efficiency, the compact form is used, though the p-adic form may
++ be gotten by calling the function padicFraction}. For a
++ general euclidean domain, it is not known how to factor the
++ denominator. Thus the function partialFraction takes as its
++ second argument an element of \spadtype{Factored(R)}.

PartialFraction(R: EuclideanDomain): Cat == Capsule where
  FRR ==> Factored R
  SUPR ==> SparseUnivariatePolynomial R

  Cat == Join(Field, Algebra R) with
    coerce: % -> Fraction R
    ++ coerce(p) sums up the components of the partial fraction and
    ++ returns a single fraction.
    ++
    ++X a:=(13/74)::PFR(INT)
    ++X a::FRAC(INT)

  coerce: Fraction FRR -> %
    ++ coerce(f) takes a fraction with numerator and denominator in
    ++ factored form and creates a partial fraction. It is

```

```

++ necessary for the parts to be factored because it is not
++ known in general how to factor elements of \spad{R} and
++ this is needed to decompose into partial fractions.
++
++X (13/74)::PFR(INT)

compactFraction: % -> %
++ compactFraction(p) normalizes the partial fraction \spad{p}
++ to the compact representation. In this form, the partial
++ fraction has only one fractional term per prime in the
++ denominator.
++
++X a:=partialFraction(1,factorial 10)
++X b:=padicFraction(a)
++X compactFraction(b)

firstDenom: % -> FRR
++ firstDenom(p) extracts the denominator of the first fractional
++ term. This returns 1 if there is no fractional part (use
++ wholePart from PartialFraction to get the whole part).
++
++X a:=partialFraction(1,factorial 10)
++X firstDenom(a)

firstNumer: % -> R
++ firstNumer(p) extracts the numerator of the first fractional
++ term. This returns 0 if there is no fractional part (use
++ wholePart from PartialFraction to get the whole part).
++
++X a:=partialFraction(1,factorial 10)
++X firstNumer(a)

nthFractionalTerm: (%,Integer) -> %
++ nthFractionalTerm(p,n) extracts the nth fractional term from
++ the partial fraction \spad{p}. This returns 0 if the index
++ \spad{n} is out of range.
++
++X a:=partialFraction(1,factorial 10)
++X b:=padicFraction(a)
++X nthFractionalTerm(b,3)

numberOfFractionalTerms: % -> Integer
++ numberOfFractionalTerms(p) computes the number of fractional
++ terms in \spad{p}. This returns 0 if there is no fractional
++ part.
++
++X a:=partialFraction(1,factorial 10)
++X b:=padicFraction(a)
++X numberOfFractionalTerms(b)

```

```

padicallyExpand: (R,R) -> SUPR
++ padicallyExpand(p,x) is a utility function that expands
++ the second argument \spad{x} 'p-adically' in
++ the first.

padicFraction: % -> %
++ padicFraction(q) expands the fraction p-adically in the primes
++ \spad{p} in the denominator of \spad{q}. For example,
++ \spad{padicFraction(3/(2**2)) = 1/2 + 1/(2**2)}.
++ Use compactFraction from PartialFraction to
++ return to compact form.
++
++X a:=partialFraction(1,factorial 10)
++X padicFraction(a)

partialFraction: (R, FRR) -> %
++ partialFraction(numer,denom) is the main function for
++ constructing partial fractions. The second argument is the
++ denominator and should be factored.
++
++X partialFraction(1,factorial 10)

wholePart: % -> R
++ wholePart(p) extracts the whole part of the partial fraction
++ \spad{p}.
++
++X a:=(74/13)::PFR(INT)
++X wholePart(a)

++ \spad{a ** b} returns the pattern \spad{a ** b}.
"/" : (% , %) -> %
++ \spad{a / b} returns the pattern \spad{a / b}.
depth : % -> NonNegativeInteger
++ depth(p) returns the nesting level of p.
convert : List % -> %
++ \spad{convert([a1,...,an])} returns the pattern \spad{[a1,...,an]}.
copy : % -> %
++ copy(p) returns a recursive copy of p.
inR? : % -> B
++ inR?(p) tests if p is an atom (i.e. an element of R).
quoted? : % -> B
++ quoted?(p) tests if p is of the form 's for a symbol s.
symbol? : % -> B
++ symbol?(p) tests if p is a symbol.
constant? : % -> B
++ constant?(p) tests if p contains no matching variables.
generic? : % -> B
++ generic?(p) tests if p is a single matching variable.
multiple? : % -> B
++ multiple?(p) tests if p is a single matching variable
++ allowing list matching or multiple term matching in a
++ sum or product.
optional? : % -> B
++ optional?(p) tests if p is a single matching variable
++ which can match an identity.
hasPredicate?: % -> B
++ hasPredicate?(p) tests if p has predicates attached to it.
predicates : % -> List Any
++ predicates(p) returns \spad{[p1,...,pn]} such that the predicate
++ attached to p is p1 and ... and pn.
setPredicates: (% , List Any) -> %
++ \spad{setPredicates(p, [p1,...,pn])} attaches the predicate
++ p1 and ... and pn to p.
withPredicates:(% , List Any) -> %
++ \spad{withPredicates(p, [p1,...,pn])} makes a copy of p and attaches
++ the predicate p1 and ... and pn to the copy, which is
++ returned.
patternVariable: (SY, B, B, B) -> %
++ patternVariable(x, c?, o?, m?) creates a pattern variable x,
++ which is constant if \spad{c? = true}, optional if \spad{o? = true},
++ and multiple if \spad{m? = true}.
setTopPredicate: (% , List SY, Any) -> %
++ \spad{setTopPredicate(x, [a1,...,an], f)} returns x with
++ the top-level predicate set to \spad{f(a1,...,an)}.
topPredicate: % -> Record(var:List SY, pred:Any)

```

```

    ++ topPredicate(x) returns \spad{[[a1,...,an], f]} where the top-level
    ++ predicate of x is \spad{f(a1,...,an)}.
    ++ Note: n is 0 if x has no top-level
    ++ predicate.
hasTopPredicate?: % -> B
    ++ hasTopPredicate?(p) tests if p has a top-level predicate.
resetBadValues: % -> %
    ++ resetBadValues(p) initializes the list of "bad values" for p
    ++ to \spad{[]}.
    ++ Note: p is not allowed to match any of its "bad values".
addBadValue: (% , Any) -> %
    ++ addBadValue(p, v) adds v to the list of "bad values" for p.
    ++ Note: p is not allowed to match any of its "bad values".
getBadValues: % -> List Any
    ++ getBadValues(p) returns the list of "bad values" for p.
    ++ Note: p is not allowed to match any of its "bad values".
variables: % -> List %
    ++ variables(p) returns the list of matching variables
    ++ appearing in p.
optpair: List % -> Union(List %, "failed")
    ++ optpair(l) returns l has the form \spad{[a, b]} and
    ++ a is optional, and
    ++ "failed" otherwise;

)abbrev domain PERM Permutation
++ Authors: Johannes Grabmeier, Holger Gollan, Martin Rubey
++ Date Created: 19 May 1989
++ Date Last Updated: 2 June 2006
++ Reference: G. James/A. Kerber: The Representation Theory of the Symmetric
++ Group. Encycl. of Math. and its Appl., Vol. 16., Cambridge
++ Description:
++ Permutation(S) implements the group of all bijections
++ on a set S, which move only a finite number of points.
++ A permutation is considered as a map from S into S. In particular
++ multiplication is defined as composition of maps:\br
++  $\pi_1 * \pi_2 = \pi_1 \circ \pi_2$ .\br
++ The internal representation of permutations are two lists
++ of equal length representing preimages and images.

Permutation(S:SetCategory): public == private where

B      ==> Boolean
PI     ==> PositiveInteger
I      ==> Integer
L      ==> List

=====
PermutationGroup examples
=====
```

PermutationGroup implements permutation groups acting on a set S , i.e. all subgroups of the symmetric group of S , represented as a list of permutations (generators). Note that therefore the objects are not members of the Axiom category Group.

Using the idea of base and strong generators by Sims, basic routines and algorithms are implemented so that the word problem for permutation groups can be solved.

public ==> SetCategory with

coerce          : %          -> L PERM S
  ++ coerce(gp) returns the generators of the group gp.
generators      : %          -> L PERM S
  ++ generators(gp) returns the generators of the group gp.
elt             : (% ,NNI)    -> PERM S
  ++ elt(gp,i) returns the i-th generator of the group gp.
random          : (% ,I)      -> PERM S
  ++ random(gp,i) returns a random product of maximal i generators
  ++ of the group gp.
random          : %          -> PERM S
  ++ random(gp) returns a random product of maximal 20 generators
  ++ of the group gp.
  ++ Note: random(gp)=random(gp,20).
order           : %          -> NNI
  ++ order(gp) returns the order of the group gp.
degree          : %          -> NNI
  ++ degree(gp) returns the number of points moved by all permutations
  ++ of the group gp.
base            : %          -> L S
  ++ base(gp) returns a base for the group gp.
strongGenerators : %          -> L PERM S
  ++ strongGenerators(gp) returns strong generators for
  ++ the group gp.
wordsForStrongGenerators : %          -> L L NNI
  ++ wordsForStrongGenerators(gp) returns the words for the strong
  ++ generators of the group gp in the original generators of
  ++ gp, represented by their indices in the list, given by
  ++ generators.
coerce          : L PERM S -> %
  ++ coerce(ls) coerces a list of permutations ls to the group
  ++ generated by this list.
permutationGroup : L PERM S -> %
  ++ permutationGroup(ls) coerces a list of permutations ls to
  ++ the group generated by this list.
orbit           : (% ,S)      -> FSET S
  ++ orbit(gp,el) returns the orbit of the element el under the
  ++ group gp, i.e. the set of all points gained by applying
  ++ each group element to el.
orbits          : %          -> FSET FSET S
  ++ orbits(gp) returns the orbits of the group gp, i.e.
  ++ it partitions the (finite) of all moved points.
orbit           : (% ,FSET S)-> FSET FSET S
  ++ orbit(gp,els) returns the orbit of the unordered
  ++ set els under the group gp.
orbit           : (% ,L S)    -> FSET L S
  ++ orbit(gp,ls) returns the orbit of the ordered
  ++ list ls under the group gp.
  ++ Note: return type is L L S temporarily because FSET L S has an error.

```

```

-- (GILT DAS NOCH?)
member?      : (PERM S, %)-> B
  ++ member?(pp, gp) answers the question, whether the
  ++ permutation pp is in the group gp or not.
wordInStrongGenerators : (PERM S, %)-> L NNI
  ++ wordInStrongGenerators(p, gp) returns the word for the
  ++ permutation p in the strong generators of the group gp,
  ++ represented by the indices of the list, given by strongGenerators.
wordInGenerators : (PERM S, %)-> L NNI
  ++ wordInGenerators(p, gp) returns the word for the permutation p
  ++ in the original generators of the group gp,
  ++ represented by the indices of the list, given by generators.
movedPoints  : %      -> FSET S
  ++ movedPoints(gp) returns the points moved by the group gp.
"<"          : (% , %)  -> B
  ++ gp1 < gp2 returns true if and only if gp1
  ++ is a proper subgroup of gp2.
"<="         : (% , %)  -> B
  ++ gp1 <= gp2 returns true if and only if gp1
  ++ is a subgroup of gp2.
  ++ Note: because of a bug in the parser you have to call this
  ++ function explicitly by gp1 <= $(PERMGRP S) gp2.
-- (GILT DAS NOCH?)
initializeGroupForWordProblem : %      -> Void
  ++ initializeGroupForWordProblem(gp) initializes the group gp
  ++ for the word problem.
  ++ Notes: it calls the other function of this name with parameters
  ++ 0 and 1: initializeGroupForWordProblem(gp, 0, 1).
  ++ Notes: (1) be careful: invoking this routine will destroy the
  ++ possibly information about your group (but will recompute it again)
  ++ (2) users need not call this function normally for the solution of
  ++ the word problem.
initializeGroupForWordProblem : (% , I, I) -> Void
  ++ initializeGroupForWordProblem(gp, m, n) initializes the group
  ++ gp for the word problem.
  ++ Notes: (1) with a small integer you get shorter words, but the
  ++ routine takes longer than the standard routine for longer words.
  ++ (2) be careful: invoking this routine will destroy the possibly stored
  ++ information about your group (but will recompute it again).
  ++ (3) users need not call this function normally for the solution of
  ++ the word problem.

domain HACKPI Pi

What is the purpose of the HACKPI domain?

HACKPI is a hack provided for the benefit of the axiom interpreter. As a mathematical type, it is the simple transcendental extension $\mathbb{Q}(\pi)$ of the rational numbers. This type allows interactive users to use the name '%pi' without a type both where a numerical value is expected [as in `draw(sin x,x=-%pi..%pi)`] or when the exact symbolic value is meant. The interpreter defaults a typeless %pi to HACKPI and then uses the various conversions to cast it further as required by the context.

One could argue that it is unfair to single %pi out from other constants, but it occurs frequently enough in school examples (specially for graphs) so it was worth a special hack. In a non-interactive environment (library), HACKPI would not exist.

```

)abbrev domain ACPLOT PlaneAlgebraicCurvePlot
++ Author: Clifton J. Williamson and Timothy Daly
++ Date Created: Fall 1988
++ Date Last Updated: 27 April 1990

```

```

++ Description:
++ Plot a NON-SINGULAR plane algebraic curve  $p(x,y) = 0$ .

PlaneAlgebraicCurvePlot(): PlottablePlaneCurveCategory _
with

makeSketch:(Polynomial Integer,Symbol,Symbol,Segment Fraction Integer,_
              Segment Fraction Integer) -> %
    ++ makeSketch(p,x,y,a..b,c..d) creates an ACLOT of the
    ++ curve \spad{p = 0} in the region  $a \leq x \leq b$ ,  $c \leq y \leq d$ .
    ++ More specifically, 'makeSketch' plots a non-singular algebraic curve
    ++ \spad{p = 0} in an rectangular region  $xMin \leq x \leq xMax$ ,
    ++  $yMin \leq y \leq yMax$ . The user inputs
    ++ \spad{makeSketch(p,x,y,xMin..xMax,yMin..yMax)}.
    ++ Here p is a polynomial in the variables x and y with
    ++ integer coefficients (p belongs to the domain
    ++ \spad{Polynomial Integer}). The case
    ++ where p is a polynomial in only one of the variables is
    ++ allowed. The variables x and y are input to specify the
    ++ the coordinate axes. The horizontal axis is the x-axis and
    ++ the vertical axis is the y-axis. The rational numbers
    ++ xMin,...,yMax specify the boundaries of the region in
    ++ which the curve is to be plotted.
    ++
    ++X makeSketch(x+y,x,y,-1/2..1/2,-1/2..1/2)$ACLOT

refine:(%,DoubleFloat) -> %
    ++ refine(p,x) is not documented
    ++
    ++X sketch:=makeSketch(x+y,x,y,-1/2..1/2,-1/2..1/2)$ACLOT
    ++X refined:=refine(sketch,0.1)

=====

Plot examples

=====

The Plot (PLOT) domain supports plotting of functions defined over a real number system. Plot is limited to 2 dimensional plots.

The function plot: (F -> F,R) -> % plots the function f(x) on the interval a..b. So we need to define a function that maps from DoubleFloat to DoubleFloat:

```
fp:=(t:DFLOAT):DFLOAT +-> sin(t)
```

and then feed it to the plot function with a Segment DoubleFloat

```
plot(fp,-1.0..1.0)$PLOT
```

)abbrev domain PLOT Plot
++ Author: Michael Monagan (revised by Clifton J. Williamson)
++ Date Created: Jan 1988
++ Date Last Updated: 30 Nov 1990 by Jonathan Steinbach
++ Description:
++ The Plot domain supports plotting of functions defined over a
++ real number system. A real number system is a model for the real
++ numbers and as such may be an approximation. For example
++ floating point numbers and infinite continued fractions.
++ The facilities at this point are limited to 2-dimensional plots
++ or either a single function or a parametric function.
  
```

```

--% function plots

plot: (F -> F,R) -> %
++ plot(f,a..b) plots the function \spad{f(x)}
++ on the interval \spad{[a,b]}.
++
++X fp:=(t:DFLOAT):DFLOAT +-> sin(t)
++X plot(fp,-1.0..1.0)$PLOT

plot: (F -> F,R,R) -> %
++ plot(f,a..b,c..d) plots the function \spad{f(x)} on the interval
++ \spad{[a,b]}; y-range of \spad{[c,d]} is noted in Plot object.

--% multiple function plots

plot: (L(F -> F),R) -> %
++ plot([f1,...,fm],a..b) plots the functions \spad{y = f1(x)},...,
++ \spad{y = fm(x)} on the interval \spad{a..b}.
plot: (L(F -> F),R,R) -> %
++ plot([f1,...,fm],a..b,c..d) plots the functions \spad{y = f1(x)},...,
++ \spad{y = fm(x)} on the interval \spad{a..b}; y-range of \spad{[c,d]} is
++ noted in Plot object.

--% parametric plots

plot: (F -> F,F -> F,R) -> %
++ plot(f,g,a..b) plots the parametric curve \spad{x = f(t)},
++ \spad{y = g(t)} as t ranges over the interval \spad{[a,b]}.
plot: (F -> F,F -> F,R,R,R) -> %
++ plot(f,g,a..b,c..d,e..f) plots the parametric curve \spad{x = f(t)},
++ \spad{y = g(t)} as t ranges over the interval \spad{[a,b]}; x-range
++ of \spad{[c,d]} and y-range of \spad{[e,f]} are noted in Plot object.

--% parametric plots

pointPlot: (F -> P,R) -> %
++ pointPlot(t +-> (f(t),g(t)),a..b) plots the parametric curve
++ \spad{x = f(t)}, \spad{y = g(t)} as t ranges over the interval
++ \spad{[a,b]}.
pointPlot: (F -> P,R,R,R) -> %

```

```

++ pointPlot(t --> (f(t),g(t)),a..b,c..d,e..f) plots the parametric
++ curve \spad{x = f(t)}, \spad{y = g(t)} as t ranges over the interval
++ \spad{[a,b]}; x-range of \spad{[c,d]} and y-range of \spad{[e,f]}
++ are noted in Plot object.

--% polar plots

plotPolar: (F -> F,R) -> %
++ plotPolar(f,a..b) plots the polar curve \spad{r = f(theta)} as
++ theta ranges over the interval \spad{[a,b]}; this is the same as
++ the parametric curve \spad{x = f(t)*cos(t)}, \spad{y = f(t)*sin(t)}.

plotPolar: (F -> F) -> %
++ plotPolar(f) plots the polar curve \spad{r = f(theta)} as theta
++ ranges over the interval \spad{[0,2*pi]}; this is the same as
++ the parametric curve \spad{x = f(t)*cos(t)}, \spad{y = f(t)*sin(t)}.

plot: (% ,R) -> %          -- change the range
++ plot(x,r) is not documented
parametric?: % -> B
++ parametric? determines whether it is a parametric plot?

zoom: (% ,R) -> %
++ zoom(x,r) is not documented
zoom: (% ,R,R) -> %
++ zoom(x,r,s) is not documented
refine: (% ,R) -> %
++ refine(x,r) is not documented
refine: % -> %
++ refine(p) performs a refinement on the plot p

tRange: % -> R
++ tRange(p) returns the range of the parameter in a parametric plot p

minPoints: () -> I
++ minPoints() returns the minimum number of points in a plot
setMinPoints: I -> I
++ setMinPoints(i) sets the minimum number of points in a plot to i
maxPoints: () -> I
++ maxPoints() returns the maximum number of points in a plot
setMaxPoints: I -> I
++ setMaxPoints(i) sets the maximum number of points in a plot to i
screenResolution: () -> I
++ screenResolution() returns the screen resolution
setScreenResolution: I -> I
++ setScreenResolution(i) sets the screen resolution to i
adaptive?: () -> B
++ adaptive?() determines whether plotting be done adaptively
setAdaptive: B -> B
++ setAdaptive(true) turns adaptive plotting on

```

```

    ++ \spad{setAdaptive(false)} turns adaptive plotting off
numFunEvals: () -> I
    ++ numFunEvals() returns the number of points computed
debug: B -> B
    ++ debug(true) turns debug mode on
    ++ \spad{debug(false)} turns debug mode off

++ Author: Clifton J. Williamson based on code by Michael Monagan
++ Date Created: Jan 1989
++ Date Last Updated: 22 November 1990 (Jon Steinbach)
++ Description:
++ Plot3D supports parametric plots defined over a real
++ number system. A real number system is a model for the real
++ numbers and as such may be an approximation. For example,
++ floating point numbers and infinite continued fractions are
++ real number systems. The facilities at this point are limited
++ to 3-dimensional parametric plots.

Plot3D(): Exports == Implementation where
  B ==> Boolean
  F ==> DoubleFloat
  I ==> Integer
  L ==> List
  N ==> NonNegativeInteger
  OUT ==> OutputForm
  P ==> Point F
  S ==> String
  R ==> Segment F
  O ==> OutputPackage
  C ==> Record(source: F -> P, ranges: L R, knots: L F, points: L P)

Exports ==> PlottableSpaceCurveCategory with

  pointPlot: (F -> P,R) -> %
    ++ pointPlot(f,g,h,a..b) plots {/emx = f(t), y = g(t), z = h(t)} as
    ++ t ranges over {/em[a,b]}.
  pointPlot: (F -> P,R,R,R,R) -> %
    ++ pointPlot(f,x,y,z,w) is not documented
  plot: (F -> F,F -> F,F -> F,F -> F,R) -> %
    ++ plot(f,g,h,a..b) plots {/emx = f(t), y = g(t), z = h(t)} as
    ++ t ranges over {/em[a,b]}.
  plot: (F -> F,F -> F,F -> F,F -> F,R,R,R,R) -> %
    ++ plot(f1,f2,f3,f4,x,y,z,w) is not documented

  plot: (% ,R) -> % -- change the range
    ++ plot(x,r) is not documented
  zoom: (% ,R,R,R) -> %
    ++ zoom(x,r,s,t) is not documented
  refine: (% ,R) -> %
    ++ refine(x,r) is not documented
  refine: % -> %
    ++ refine(x) is not documented

  tRange: % -> R
    ++ tRange(p) returns the range of the parameter in a parametric plot p.
  tValues: % -> L L F

```

```

++ tValues(p) returns a list of lists of the values of the parameter for
++ which a point is computed, one list for each curve in the plot p.

minPoints3D: () -> I
++ minPoints3D() returns the minimum number of points in a plot.
setMinPoints3D: I -> I
++ setMinPoints3D(i) sets the minimum number of points in a plot to i.
maxPoints3D: () -> I
++ maxPoints3D() returns the maximum number of points in a plot.
setMaxPoints3D: I -> I
++ setMaxPoints3D(i) sets the maximum number of points in a plot to i.
screenResolution3D: () -> I
++ screenResolution3D() returns the screen resolution for a 3d graph.
setScreenResolution3D: I -> I
++ setScreenResolution3D(i) sets the screen resolution for a 3d graph to i.
adaptive3D?: () -> B
++ adaptive3D?() determines whether plotting be done adaptively.
setAdaptive3D: B -> B
++ setAdaptive3D(true) turns adaptive plotting on;
++ setAdaptive3D(false) turns adaptive plotting off.
numFunEvals3D: () -> I
++ numFunEvals3D() returns the number of points computed.
debug3D: B -> B
++ debug3D(true) turns debug mode on;
++ debug3D(false) turns debug mode off.

Polynomial examples

Type: Polynomial Float

And here we have a polynomial in two variables with coefficients which have type Fraction Integer.

$$y^2 - z + \frac{3}{4} - z^2 + y^3 - \frac{1}{4}$$

Type: Polynomial Fraction Integer

The representation of objects of domains created by Polynomial is that of recursive univariate polynomials. The term univariate means "one variable". The term multivariate means "possibly more than one variable".

This recursive structure is sometimes obvious from the display of a polynomial.

$$y^2 + x^2y + y^2 + (x+1)y$$

Type: Polynomial Integer

In this example, you see that the polynomial is stored as a polynomial in y with coefficients that are polynomials in x with integer coefficients. In fact, you really don't need to worry about the representation unless you are working on an advanced application where it is critical. The polynomial types created from DistributedMultivariatePolynomial and NewDistributedMultivariatePolynomial are stored and displayed in a non-recursive manner.

You see a "flat" display of the above polynomial by converting to one of those types.

$$\% :: \text{DMP}([y,x], \text{INT})$$

$$y^2 + yx + y^2$$

Type: DistributedMultivariatePolynomial([y,x], Integer)

We will demonstrate many of the polynomial facilities by using two polynomials with integer coefficients.

By default, the interpreter expands polynomial expressions, even if they are written in a factored format.

$$p := (y-1)^2 * x * z$$

$$(x y^2 - 2x y + x)z$$

Type: Polynomial Integer

See Factored to see how to create objects in factored form directly.

$$q := (y-1) * x * (z+5)$$

```
(x y - x)z + 5x y - 5x
      Type: Polynomial Integer
```

The fully factored form can be recovered by using factor.

```
factor(q)
x(y - 1)(z + 5)
      Type: Factored Polynomial Integer
```

This is the same name used for the operation to factor integers. Such reuse of names is called overloading and makes it much easier to think of solving problems in general ways. Axiom facilities for factoring polynomials created with Polynomial are currently restricted to the integer and rational number coefficient cases.

The standard arithmetic operations are available for polynomials.

```
p - q**2
      2 2      2      2 2      2      2      2      2
      (- x y + 2x y - x )z + ((- 10x + x)y + (20x - 2x)y - 10x + x)z
+
      2 2      2      2
      - 25x y + 50x y - 25x
      Type: Polynomial Integer
```

The operation gcd is used to compute the greatest common divisor of two polynomials.

```
gcd(p,q)
x y - x
      Type: Polynomial Integer
```

In the case of p and q, the gcd is obvious from their definitions. We factor the gcd to show this relationship better.

```
factor %
x(y - 1)
      Type: Factored Polynomial Integer
```

The least common multiple is computed by using lcm.

```
lcm(p,q)
      2      2      2
      (x y - 2x y + x)z + (5x y - 10x y + 5x)z
      Type: Polynomial Integer
```

Use content to compute the greatest common divisor of the coefficients of the polynomial.

```
content p
```

1

Type: PositiveInteger

Many of the operations on polynomials require you to specify a variable. For example, resultant requires you to give the variable in which the polynomials should be expressed.

This computes the resultant of the values of p and q, considering them as polynomials in the variable z. They do not share a root when thought of as polynomials in z.

```
resultant(p,q,z)
      2 3      2 2      2      2
      5x y  - 15x y  + 15x y  - 5x
                                     Type: Polynomial Integer
```

This value is 0 because as polynomials in x the polynomials have a common root.

```
resultant(p,q,x)
0
                                     Type: Polynomial Integer
```

The data type used for the variables created by Polynomial is Symbol. As mentioned above, the representation used by Polynomial is recursive and so there is a main variable for nonconstant polynomials.

The operation mainVariable returns this variable. The return type is actually a union of Symbol and "failed".

```
mainVariable p
z
                                     Type: Union(Symbol,...)
```

The latter branch of the union is be used if the polynomial has no variables, that is, is a constant.

```
mainVariable(1 :: POLY INT)
"failed"
                                     Type: Union("failed",...)
```

You can also use the predicate ground? to test whether a polynomial is in fact a member of its ground ring.

```
ground? p
false
                                     Type: Boolean
```

```
ground?(1 :: POLY INT)
true
```

Type: Boolean

The complete list of variables actually used in a particular polynomial is returned by `variables`. For constant polynomials, this list is empty.

```
variables p
[z,y,x]
```

Type: List Symbol

The degree operation returns the degree of a polynomial in a specific variable.

```
degree(p,x)
1
```

Type: PositiveInteger

```
degree(p,y)
2
```

Type: PositiveInteger

```
degree(p,z)
1
```

Type: PositiveInteger

If you give a list of variables for the second argument, a list of the degrees in those variables is returned.

```
degree(p,[x,y,z])
[1,2,1]
```

Type: List NonNegativeInteger

The minimum degree of a variable in a polynomial is computed using `minimumDegree`.

```
minimumDegree(p,z)
1
```

Type: PositiveInteger

The total degree of a polynomial is returned by `totalDegree`.

```
totalDegree p
4
```

Type: PositiveInteger

It is often convenient to think of a polynomial as a leading monomial plus the remaining terms.

```
leadingMonomial p
2
x y z
```

Type: Polynomial Integer

Derivatives are computed using the D operation.

```
D(p,x)
  2
  (y  - 2y + 1)z
      Type: Polynomial Integer
```

The first argument is the polynomial and the second is the variable.

```
D(p,y)
  (2x y - 2x)z
      Type: Polynomial Integer
```

Even if the polynomial has only one variable, you must specify it.

```
D(p,z)
  2
  x y  - 2x y + x
      Type: Polynomial Integer
```

Integration of polynomials is similar and the integrate operation is used.

Integration requires that the coefficients support division. Axiom converts polynomials over the integers to polynomials over the rational numbers before integrating them.

```
integrate(p,y)
  1   3   2
  (- x y  - x y  + x y)z
  3
      Type: Polynomial Fraction Integer
```

It is not possible, in general, to divide two polynomials. In our example using polynomials over the integers, the operation `monicDivide` divides a polynomial by a monic polynomial (that is, a polynomial with leading coefficient equal to 1). The result is a record of the quotient and remainder of the division.

You must specify the variable in which to express the polynomial.

```
qr := monicDivide(p,x+1,x)
      2               2
[quotient= (y  - 2y + 1)z,remainder= (- y  + 2y - 1)z]
      Type: Record(quotient: Polynomial Integer,remainder: Polynomial Integer)
```

The selectors of the components of the record are `quotient` and `remainder`. Issue this to extract the remainder.

```
qr.remainder
  2
```

$$(-y^2 + 2y - 1)z$$

Type: Polynomial Integer

Now that we can extract the components, we can demonstrate the relationship among them and the arguments to our original expression

```
qr := monicDivide(p,x+1,x).
```

```
p - ((x+1) * qr.quotient + qr.remainder)
0
```

Type: Polynomial Integer

If the / operator is used with polynomials, a fraction object is created. In this example, the result is an object of type Fraction Polynomial Integer.

$$\frac{p/q}{(y-1)z}$$

$$\frac{z+5}{z+5}$$

Type: Fraction Polynomial Integer

If you use rational numbers as polynomial coefficients, the resulting object is of type Polynomial Fraction Integer.

$$\frac{(2/3) * x^2 - y + 4/5}{-y + \frac{2}{3}x^2 + \frac{4}{5}}$$

Type: Polynomial Fraction Integer

This can be converted to a fraction of polynomials and back again, if required.

```
% :: FRAC POLY INT
      2
- 15y + 10x + 12
-----
      15
```

Type: Fraction Polynomial Integer

```
% :: POLY FRAC INT
      2 2 4
- y + - x + -
      3 5
```

Type: Polynomial Fraction Integer

To convert the coefficients to floating point, map the numeric operation on the coefficients of the polynomial.

```
map(numeric,%)
```

```
- 1.0 y + 0.6666666666 6666666667 x + 0.8
Type: Polynomial Float
```

PolynomialIdeals examples

=====

This domain represents polynomial ideals with coefficients in any field and supports the basic ideal operations, including intersection sum and quotient.

An ideal is represented by a list of polynomials (the generators of the ideal) and a boolean that is true if the generators are a Groebner basis.

The algorithms used are based on Groebner basis computations. The ordering is determined by the datatype of the input polynomials. Users may use refinements of total degree orderings.

generators      :      Ideal      -> List DPoly
++ generators(I) returns a list of generators for the ideal I.
coerce          :      List DPoly      -> Ideal
++ coerce(polyList) converts the list of polynomials polyList
++ to an ideal.

saturate        : (Ideal,DPoly)      -> Ideal
++ saturate(I,f) is the saturation of the ideal I
++ with respect to the multiplicative
++ set generated by the polynomial f.
saturate        : (Ideal,DPoly,List VarSet) -> Ideal
++ saturate(I,f,lvar) is the saturation with respect to the prime
++ principal ideal which is generated by f in the polynomial ring
++ \spad{F[lvar]}.
if VarSet has ConvertibleTo Symbol then
  relationsIdeal :      List DPoly      -> ST
  ++ relationsIdeal(polyList) returns the ideal of relations among the
  ++ polynomials in polyList.

PolynomialRing examples

=====

This domain represents generalized polynomials with coefficients (from a not necessarily commutative ring), and terms indexed by their exponents (from an arbitrary ordered abelian monoid).

This type is used, for example, by the DistributedMultivariatePolynomial domain where the exponent domain is a direct product of non negative integers.

=====

Product examples

=====

The direct product of two functions over the same domain is another function over that domain whose co-domain is the product of their co-domains.

So we can define two functions, f and g , that go from $\text{INT} \rightarrow \text{INT}$

```
f:=(x:INT):INT +-> 3*x
g:=(x:INT):INT +-> x^3
```

so

```
f(3) is 9
g(3) is 27
```

and we can construct the direct product of those functions $h=f,g$

```
h(x:INT):Product(INT,INT) == makeprod(f x, g x)
```

so

```
h(3) is (9,27)
```

```

This domain implement dynamic extension over the
PseudoAlgebraicClosureOfRationalNumber.

A tower extension T of the ground field K is any sequence of field
extension

$(T : K_0, K_1, \dots, K_i, \dots, K_n)$

where $K_0 = K$ and for $i = 1, 2, \dots, n$, K_i is an extension of
 K_{i-1} of degree > 1 and defined by an irreducible polynomial
 $p(Z)$ in K_{i-1} .

Two towers

$(T_1: K_{01}, K_{11}, \dots, K_{i1}, \dots, K_{n1})$

and

$(T_2: K_{02}, K_{12}, \dots, K_{i2}, \dots, K_{n2})$

are said to be related if

$T_1 \leq T_2$ (or $T_1 \geq T_2$),

that is if

$K_{i1} = K_{i2}$ for $i = 1, 2, \dots, n1$

(or $i = 1, 2, \dots, n2$). Any algebraic operations defined for several elements
are only defined if all of the concerned elements are coming from

a set of related tour extensions.

PseudoAlgebraicClosureOfFiniteField examples
=====
```

This domain implement dynamic extension using the simple notion of tower extensions. A tower extension T of the ground field K is any sequence of field extension

($T : K_0, K_1, \dots, K_i, \dots, K_n$)

where $K_0 = K$ and for $i = 1, 2, \dots, n$, K_i is an extension of K_{i-1} of degree > 1 and defined by an irreducible polynomial $p(Z)$ in K_{i-1} .

Two towers

($T_1: K_{01}, K_{11}, \dots, K_{i1}, \dots, K_{n1}$)

and

($T_2: K_{02}, K_{12}, \dots, K_{i2}, \dots, K_{n2}$)

are said to be related if

$T_1 \leq T_2$ (or $T_1 \geq T_2$),

that is if

$K_{i1} = K_{i2}$ for $i=1, 2, \dots, n1$

(or $i=1, 2, \dots, n2$). Any algebraic operations defined for several elements are only defined if all of the concerned elements are coming from a set of related tower extensions.

)abbrev domain PACOFF PseudoAlgebraicClosureOfFiniteField
++ Authors: Gaetan Hache
++ Date Created: june 1996
++ Date Last Updated: May 2010 by Tim Daly
++ Description:
++ This domain implement dynamic extension using the simple notion of
++ tower extensions. A tower extension T of the ground field K is any
++ sequence of field extension (T : K_0, K_1, ..., K_i...,K_n) where K_0 = K
++ and for i =1,2,...,n, K_i is an extension of K_{i-1} of degree > 1 and
++ defined by an irreducible polynomial p(Z) in K_{i-1}.
++ Two towers (T_1: K_01, K_11,...,K_i1,...,K_n1)
++ and (T_2: K_02, K_12,...,K_i2,...,K_n2) are said to be related
++ if T_1 <= T_2 (or T_1 >= T_2), that is if K_i1 = K_i2 for i=1,2,...,n1
++ (or i=1,2,...,n2). Any algebraic operations defined for several elements
++ are only defined if all of the concerned elements are coming from
++ a set of related tower extensions.

PseudoAlgebraicClosureOfRationalNumber examples
=====

```

This domain implements dynamic extension using the simple notion of tower extensions. A tower extension T of the ground field K is any sequence of field extension

$(T : K_0, K_1, \dots, K_{i-1}, K_i, \dots, K_n)$

where $K_0 = K$ and for $i = 1, 2, \dots, n$, K_i is an extension of K_{i-1} of degree > 1 and defined by an irreducible polynomial $p(Z)$ in K_{i-1} .

Two towers

$(T_1: K_{01}, K_{11}, \dots, K_{i1}, \dots, K_{n1})$

and

$(T_2: K_{02}, K_{12}, \dots, K_{i2}, \dots, K_{n2})$

are said to be related if

$T_1 \leq T_2$ (or $T_1 \geq T_2$),

that is if

$K_{i1} = K_{i2}$ for $i=1, 2, \dots, n1$ (or $i=1, 2, \dots, n2$).

Any algebraic operations defined for several elements are only defined if all of the concerned elements are coming from a set of related tower

extensions.

QuasiAlgebraicSet examples

=====

QuasiAlgebraicSet constructs a domain representing quasi-algebraic sets, which is the intersection of a Zariski closed set, defined as the common zeros of a given list of polynomials (the defining polynomials for equations), and a principal Zariski open set, defined as the complement of the common zeros of a polynomial f (the defining polynomial for the inequation).

This domain provides simplification of a user-given representation using groebner basis computations.

There are two simplification routines: the first function `idealSimplify` uses groebner basis of ideals alone, while the second, `simplify` uses both groebner basis and factorization. The resulting defining equations `L` always form a groebner basis, and the resulting defining inequation `f` is always reduced. The function `simplify` may be applied several times if desired. A third simplification routine `radicalSimplify` is provided in `QuasiAlgebraicSet2` for comparison study only, as it is inefficient compared to the other two, as well as is restricted to only certain coefficient domains. For detail analysis and a comparison of the three methods, please consult the reference cited.

A polynomial function `q` defined on the quasi-algebraic set is equivalent to its reduced form with respect to `L`. While this may be obtained using the usual normal form algorithm, there is no canonical form for `q`.

The ordering in groebner basis computation is determined by the data type of the input polynomials. If it is possible we suggest to use refinements of total degree orderings.

— Quaternion.help —

Quaternion examples

The domain constructor Quaternion implements quaternions over commutative rings.

The basic operation for creating quaternions is `quatern`. This is a quaternion over the rational numbers.

```

q := quatern(2/11,-8,3/4,1)
      2      3
-- - 8i + - j + k
      11      4

```

Type: Quaternion Fraction Integer

The four arguments are the real part, the i imaginary part, the j imaginary part, and the k imaginary part, respectively.

```
[real q, imagI q, imagJ q, imagK q]
      2      3
[--, - 8, -, 1]
     11     4
```

Type: List Fraction Integer

Because q is over the rationals (and nonzero), you can invert it.

```
inv q
      352      15488      484      1936
----- + ----- i - ----- j - ----- k
126993  126993  42331  126993
Type: Quaternion Fraction Integer
```

The usual arithmetic (ring) operations are available

```
q^6
      2029490709319345      48251690851      144755072553      48251690851
- ----- - ----- i + ----- j + ----- k
      7256313856      1288408      41229056      10307264
Type: Quaternion Fraction Integer
```

```
r := quatern(-2,3,23/9,-89); q + r
      20      119
- -- - 5i + --- j - 88k
     11      36
Type: Quaternion Fraction Integer
```

In general, multiplication is not commutative.

```
q * r - r * q
      2495      817
- ---- i - 1418j - --- k
      18      18
Type: Quaternion Fraction Integer
```

There are no predefined constants for the imaginary i, j, and k parts, but you can easily define them.

```
i:=quatern(0,1,0,0)
i
Type: Quaternion Integer
```

```
j:=quatern(0,0,1,0)
j
```

Type: Quaternion Integer

```
k:=quatern(0,0,0,1)
k
```

Type: Quaternion Integer

These satisfy the normal identities.

```
[i*i, j*j, k*k, i*j, j*k, k*i, q*i]
      2      3
[- 1,- 1,- 1,k,i,j,8 + -- i + j - - k]
      11      4
```

Type: List Quaternion Fraction Integer

The norm is the quaternion times its conjugate.

```
norm q
126993
-----
1936
```

Type: Fraction Integer

```
conjugate q
      2      3
-- + 8i - - j - k
      11      4
```

Type: Quaternion Fraction Integer

```
q * %
126993
-----
1936
```

Type: Quaternion Fraction Integer

=====

Queue examples

=====

A Queue object is represented as a list ordered by first-in, first-out. It operates like a line of people, where the "next" person is the one at the front of the line.

Here we create an queue of integers from a list. Notice that the order in the list is the order in the queue.

```
a:Queue INT:= queue [1,2,3,4,5]
  [1,2,3,4,5]
```

We can remove the top of the queue using dequeue!:

```
dequeue! a
  1
```

Notice that the use of dequeue! is destructive (destructive operations in Axiom usually end with ! to indicate that the underlying data structure is changed).

```
a
  [2,3,4,5]
```

The extract! operation is another name for the pop! operation and has the same effect. This operation treats the queue as a BagAggregate:

```
extract! a
  2
```

and you can see that it also has destructively modified the queue:

```
a
  [3,4,5]
```

Next we use enqueue! to add a new element to the end of the queue:

```
push!(9,a)
  9
```

Again, the push! operation is destructive so the queue is changed:

```
a
```

```
[3,4,5,9]
```

Another name for enqueue! is insert!, which treats the queue as a BagAggregate:

```
insert!(8,a)
[3,4,5,9,8]
```

and it modifies the queue:

```
a
[3,4,5,9,8]
```

The inspect function returns the top of the queue without modification, viewed as a BagAggregate:

```
inspect a
8
```

The empty? operation returns true only if there are no element on the queue, otherwise it returns false:

```
empty? a
false
```

The front operation returns the front of the queue without modification:

```
front a
3
```

The back operation returns the back of the queue without modification:

```
back a
8
```

The rotate! operation moves the item at the front of the queue to the back of the queue:

```
rotate! a
[4,5,9,8,3]
```

The # (length) operation:

```
#a
5
```

The length operation does the same thing:

```
length a
5
```

The less? predicate will compare the queue length to an integer:

```
less?(a,9)
true
```

The more? predicate will compare the queue length to an integer:

```
more?(a,9)
false
```

The size? operation will compare the queue length to an integer:

```
size?(a,#a)
true
```

and since the last computation must always be true we try:

```
size?(a,9)
false
```

The parts function will return the queue as a list of its elements:

```
parts a
[8,9,3,4,5]
```

If we have a BagAggregate of elements we can use it to construct a queue:

```
bag([1,2,3,4,5])$Queue(INT)
[1,2,3,4,5]
```

The empty function will construct an empty queue of a given type:

```
b:=empty()$(Queue INT)
[]
```

and the empty? predicate allows us to find out if a queue is empty:

```
empty? b
true
```

The sample function returns a sample, empty queue:

```
sample()$Queue(INT)
[]
```

We can copy a queue and it does not share storage so subsequent modifications of the original queue will not affect the copy:

```
c:=copy a
```

```
[4,5,9,8,3]
```

The `eq?` function is only true if the lists are the same reference, so even though `c` is a copy of `a`, they are not the same:

```
eq?(a,c)
false
```

However, `a` clearly shares a reference with itself:

```
eq?(a,a)
true
```

But we can compare `a` and `c` for equality:

```
(a=c)@Boolean
true
```

and clearly `a` is equal to itself:

```
(a=a)@Boolean
true
```

and since `a` and `c` are equal, they are clearly NOT not-equal:

```
a~=c
false
```

We can use the `any?` function to see if a predicate is true for any element:

```
any?(x+>(x=4),a)
true
```

or false for every element:

```
any?(x+>(x=11),a)
false
```

We can use the `every?` function to check every element satisfies a predicate:

```
every?(x+>(x=11),a)
false
```

We can count the elements that are equal to an argument of this type:

```
count(4,a)
1
```

or we can count against a boolean function:

```
count(x+-(x>2),a)
5
```

You can also map a function over every element, returning a new queue:

```
map(x+>x+10,a)
[14,15,19,18,13]
```

Notice that the original queue is unchanged:

```
a
[4,5,9,8,3]
```

You can use `map!` to map a function over every element and change the original queue since `map!` is destructive:

```
map!(x+>x+10,a)
[14,15,19,18,13]
```

o

Notice that the original queue has been changed:

```
a
[14,15,19,18,13]
```

The `members` function can also get the element of the queue as a list:

```
members a
[18,19,13,14,15]
```

and using `member?` we can test if the queue holds a given element:

```
member?(14,a)
true
```

=====

RadixExpansion examples

=====

It possible to expand numbers in general bases.

Here we expand 111 in base 5. This means

$$10^2 + 10^1 + 10^0 = 4 * 5^2 + 2 * 5^1 + 5^0$$

```

111::RadixExpansion(5)
421
                                          Type: RadixExpansion 5

```

You can expand fractions to form repeating expansions.

```

(5/24)::RadixExpansion(2)
--
0.00110
                                          Type: RadixExpansion 2

```

```

(5/24)::RadixExpansion(3)
--
0.012
                                          Type: RadixExpansion 3

```

```

(5/24)::RadixExpansion(8)
--
0.152

```

Type: RadixExpansion 8

(5/24)::RadixExpansion(10)

0.2083̄

Type: RadixExpansion 10

For bases from 11 to 36 the letters A through Z are used.

(5/24)::RadixExpansion(12)

0.26

Type: RadixExpansion 12

(5/24)::RadixExpansion(16)

0.35̄

Type: RadixExpansion 16

(5/24)::RadixExpansion(36)

0.7I

Type: RadixExpansion 36

For bases greater than 36, the ragits are separated by blanks.

(5/24)::RadixExpansion(38)

0 . 7 34 31 25 12̄

Type: RadixExpansion 38

The RadixExpansion type provides operations to obtain the individual ragits. Here is a rational number in base 8.

a := (76543/210)::RadixExpansion(8)

554.37307̄

Type: RadixExpansion 8

The operation wholeRagits returns a list of the ragits for the integral part of the number.

w := wholeRagits a

[5,5,4]

Type: List Integer

The operations prefixRagits and cycleRagits return lists of the initial and repeating ragits in the fractional part of the number.

f0 := prefixRagits a

[3]

Type: List Integer

```
f1 := cycleRagits a
      [7,3,0,7]
```

Type: List Integer

You can construct any radix expansion by giving the whole, prefix and cycle parts. The declaration is necessary to let Axiom know the base of the ragits.

```
u:RadixExpansion(8):=wholeRadix(w)+fractRadix(f0,f1)
      ----
    554.37307
```

Type: RadixExpansion 8

If there is no repeating part, then the list [0] should be used.

```
v: RadixExpansion(12) := fractRadix([1,2,3,11], [0])
      -
    0.123B0
```

Type: RadixExpansion 12

If you are not interested in the repeating nature of the expansion, an infinite stream of ragits can be obtained using fractRagits.

```
fractRagits(u)
      -----
    [3,7,3,0,7,7]
```

Type: Stream Integer

Of course, it's possible to recover the fraction representation:

```
a :: Fraction(Integer)
      76543
      ----
      210
```

Type: Fraction Integer

— domain RADIX RadixExpansion —

```
)abbrev domain RADIX RadixExpansion
++ Author: Stephen M. Watt
++ Date Created: October 1986
++ Date Last Updated: May 15, 1991
++ Description:
++ This domain allows rational numbers to be presented as repeating
++ decimal expansions or more generally as repeating expansions in any base.
```

```
RadixExpansion(bb): Exports == Implementation where
  bb   : Integer
  I    ==> Integer
  NNI  ==> NonNegativeInteger
  OUT  ==> OutputForm
  RN   ==> Fraction Integer
  ST   ==> Stream Integer
  QuoRem ==> Record(quotient: Integer, remainder: Integer)
```

```

Exports ==> QuotientFieldCategory(Integer) with
  coerce: % -> Fraction Integer
    ++ coerce(rx) converts a radix expansion to a rational number.
  fractionPart: % -> Fraction Integer
    ++ fractionPart(rx) returns the fractional part of a radix expansion.
  wholeRagits: % -> List Integer
    ++ wholeRagits(rx) returns the ragits of the integer part
    ++ of a radix expansion.
  fractRagits: % -> Stream Integer
    ++ fractRagits(rx) returns the ragits of the fractional part
    ++ of a radix expansion.
  prefixRagits: % -> List Integer
    ++ prefixRagits(rx) returns the non-cyclic part of the ragits
    ++ of the fractional part of a radix expansion.
    ++ For example, if \spad{x = 3/28 = 0.10 714285 714285 ...},
    ++ then \spad{prefixRagits(x)}=[1,0]}.
  cycleRagits: % -> List Integer
    ++ cycleRagits(rx) returns the cyclic part of the ragits of the
    ++ fractional part of a radix expansion.
    ++ For example, if \spad{x = 3/28 = 0.10 714285 714285 ...},
    ++ then \spad{cycleRagits(x)} = [7,1,4,2,8,5]}.
  wholeRadix: List Integer -> %
    ++ wholeRadix(l) creates an integral radix expansion from a list
    ++ of ragits.
    ++ For example, \spad{wholeRadix([1,3,4])} will return \spad{134}.
  fractRadix: (List Integer, List Integer) -> %
    ++ fractRadix(pre,cyc) creates a fractional radix expansion
    ++ from a list of prefix ragits and a list of cyclic ragits.
    ++ e.g., \spad{fractRadix([1],[6])} will return \spad{0.16666666...}.

Implementation ==> add

domain RECLOS RealClosure

The domain constructore **RealClosure** by Renaud Rioboo (University of Paris 6, France) provides the real closure of an ordered field. The implementation is based on interval arithmetic. Moreover, the design of this constructor and its related packages allows an easy use of other codings for real algebraic numbers. ordered field

The RealClosure domain is the end-user code, it provides usual arithmetics with real algebraic numbers, along with the functionalities of a real closed field. It also provides functions to approximate a real algebraic number by an element of the base field. This approximation may either be absolute (approximate) or relative (realtivApprox).

CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any

new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like `sqrt(2) + sqrt(2)` you have two new variables which happen to be equal. To avoid this name the expression such as in `s2 := sqrt(2) ; s2 + s2`

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

LIMITATIONS

The file `reclos.input` show some basic use of the package. This package uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

=====
RealClosure examples
=====

```

The Real Closure 1.0 package provided by Renaud Rioboo consists of different packages, categories and domains :

The package `RealPolynomialUtilitiesPackage` which needs a `Field F` and a `UnivariatePolynomialCategory` domain with coefficients in `F`. It computes some simple functions such as Sturm and Sylvester sequences `sturmSequence`, `sylvesterSequence`.

The category `RealRootCharacterizationCategory` provides abstract functions to work with "real roots" of univariate polynomials. These resemble variables with some functionality needed to compute important operations.

The category `RealClosedField` provides common operations available over real closed fields. These include finding all the roots of a univariate polynomial, taking square (and higher) roots, ...

The domain `RightOpenIntervalRootCharacterization` is the main code that provides the functionality of `RealRootCharacterizationCategory` for the case of archimedean fields. Abstract roots are encoded with a left closed right open interval containing the root together with a defining polynomial for the root.

The `RealClosure` domain is the end-user code. It provides usual arithmetic with real algebraic numbers, along with the functionality of a real closed field. It also provides functions to approximate a real algebraic number by an element of the base field. This approximation may either be absolute, approximate or relative (`relativeApprox`).

CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like `sqrt(2) + sqrt(2)` you have two new variables which happen to be equal. To avoid this name the expression such as in `s2 := sqrt(2) ; s2 + s2`

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which seems most natural to you.

LIMITATIONS

This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several ‘‘real roots’’.

EXAMPLES

We shall work with the real closure of the ordered field of rational numbers.

```
Ran := RECLOS(FRAC INT)
RealClosure Fraction Integer
Type: Domain
```

Some simple signs for square roots, these correspond to an extension of degree 16 of the rational numbers. Examples provided by J. Abbot.

```
fourSquares(a:Ran,b:Ran,c:Ran,d:Ran):Ran==sqrt(a)+sqrt(b)-sqrt(c)-sqrt(d)
Type: Void
```

These produce values very close to zero.

```

— domain RECLOS RealClosure —

```
)abbrev domain RECLOS RealClosure
++ Author: Renaud Rioboo
++ Date Created: summer 1988
++ Date Last Updated: January 2004
++ Description:
++ This domain implements the real closure of an ordered field.
++ Note:
++ The code here is generic i.e. it does not depend of the way the operations
++ are done. The two macros PME and SEG should be passed as functorial
++ arguments to the domain. It does not help much to write a category
++ since non trivial methods cannot be placed there either.
++
```

=====

RegularChain examples

=====

A domain for regular chains (i.e. regular triangular sets) over
a Gcd-Domain and with a fix list of variables.

This is just a front-end for the RegularTriangularSet domain constructor.

)abbrev domain RGCHAIN RegularChain
++ Author: Marc Moreno Maza
++ Date Created: 01/1999
++ Date Last Updated: 23/01/1999
++ Description:
++ A domain for regular chains (i.e. regular triangular sets) over
++ a Gcd-Domain and with a fix list of variables.
++ This is just a front-end for the \spadtype{RegularTriangularSet}
++ domain constructor.

RegularChain(R,ls): Exports == Implementation where
  R : GcdDomain
  ls: List Symbol
  V ==> OrderedVariableList ls
  E ==> IndexedExponents V
  P ==> NewSparseMultivariatePolynomial(R,V)
  TS ==> RegularTriangularSet(R,E,V,P)

Exports == RegularTriangularSetCategory(R,E,V,P) with
  zeroSetSplit: (List P, Boolean, Boolean) -> List $
    ++ \spad{zeroSetSplit(lp,clos?,info?)} returns a list \spad{lhs} of
    ++ regular chains such that the union of the closures of their regular
    ++ zero sets equals the affine variety associated with \spad{lp}.
    ++ Moreover, if \spad{clos?} is \spad{false} then the union of the
    ++ regular zero set of the \spad{ts} (for \spad{ts} in \spad{lhs})
    ++ equals this variety.
    ++ If \spad{info?} is \spad{true} then some information is
    ++ displayed during the computations. See
    ++ zeroSetSplit from RegularTriangularSet.

Implementation == RegularTriangularSet(R,E,V,P)

```

"RGCHAIN" -> "RSETCAT"

```

Several domain constructors implement regular triangular sets (or regular chains). Among them **RegularTriangularSet** and **SquareFreeRegularTriangularSet**. They also implement an algorithm by Marc Moreno Maza for computing triangular decompositions of polynomial systems. This method is refined in the package **LazardSetSolvingPackage** in order to produce decompositions by means of Lazard triangular sets.

=====
RegularTriangularSet examples
=====
```

The RegularTriangularSet domain constructor implements regular triangular sets. These particular triangular sets were introduced by M. Kalkbrener (1991) in his PhD Thesis under the name regular chains. Regular chains and their related concepts are presented in the paper "On the Theories of Triangular sets" By P. Aubry, D. Lazard and M. Moreno Maza (to appear in the Journal of Symbolic Computation). The RegularTriangularSet constructor also provides a new method (by the third author) for solving polynomial system by means of regular chains. This method has two ways of solving. One has the same specifications as Kalkbrener's algorithm (1991) and the other is closer to Lazard's method (Discr. App. Math, 1991). Moreover, this new method removes redundant component from the decompositions when this is not too expensive. This is always the case with square-free regular chains. So if you want to obtain decompositions without redundant components just use the SquareFreeRegularTriangularSet domain constructor or the LazardSetSolvingPackage package constructor. See also the LexTriangularPackage and ZeroDimensionalSolvePackage for the case of algebraic systems with a finite number of (complex) solutions.

One of the main features of regular triangular sets is that they naturally define towers of simple extensions of a field. This allows to perform with multivariate polynomials the same kind of operations as one can do in an EuclideanDomain.

The RegularTriangularSet constructor takes four arguments. The first one, R, is the coefficient ring of the polynomials; it must belong to the category GcdDomain. The second one, E, is the exponent monoid of the polynomials; it must belong to the category OrderedAbelianMonoidSup. The third one, V, is the ordered set of variables; it must belong to the category OrderedSet. The last one is the polynomial ring; it must belong to the category RecursivePolynomialCategory(R,E,V). The abbreviation for RegularTriangularSet is REGSET. See also the constructor RegularChain which only takes two arguments, the coefficient ring and the ordered set of variables; in that case, polynomials are necessarily built with the NewSparseMultivariatePolynomial domain constructor.

We shall explain now how to use the constructor REGSET and how to read the decomposition of a polynomial system by means of regular sets.

Let us give some examples. We start with an easy one (Donati-Traverso) in order to understand the two ways of solving polynomial systems provided by the REGSET constructor.

Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the list of variables,

```
ls : List Symbol := [x,y,z,t]
[x,y,z,t]
Type: List Symbol
```

and make it an ordered set;

```
V := OVAR(ls)
OrderedVariableList [x,y,z,t]
Type: Domain
```

then define the exponent monoid.

```
E := IndexedExponents V
IndexedExponents OrderedVariableList [x,y,z,t]
Type: Domain
```

Define the polynomial ring.

```
P := NSMP(R, V)
NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])
Type: Domain
```

Let the variables be polynomial.

```
x: P := 'x
x
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])
y: P := 'y
y
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])
z: P := 'z
z
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])
```

```

t: P := 't
t
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

```

Now call the RegularTriangularSet domain constructor.

```

T := REGSET(R,E,V,P)
RegularTriangularSet(Integer,IndexedExponents OrderedVariableList [x,y,z,t],O
rderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,OrderedV
ariableList [x,y,z,t]))
Type: Domain

```

Define a polynomial system.

```

p1 := x ** 31 - x ** 6 - x - y
31 6
x - x - x - y
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

p2 := x ** 8 - z
8
x - z
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

p3 := x ** 10 - t
10
x - t
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

lp := [p1, p2, p3]
31 6 8 10
[x - x - x - y, x - z, x - t]
Type: List NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

```

First of all, let us solve this system in the sense of Kalkbrener.

```

zeroSetSplit(lp)$T
5 4 2 3 8 5 3 2 4 2
[{z - t , t z y + 2z y - t + 2t + t - t , (t - t)x - t y - z }]
Type: List RegularTriangularSet(Integer,
IndexedExponents OrderedVariableList [x,y,z,t],
OrderedVariableList [x,y,z,t],
NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t]))

```

And now in the sense of Lazard (or Wu and other authors).

```
lts := zeroSetSplit(lp,false)$T
      5      4      2      3      8      5      3      2      4      2
      [{z  - t ,t z y  + 2z y - t  + 2t  + t  - t ,(t  - t)x - t y - z },
      3      5      2      3      2
      {t  - 1,z  - t,t z y  + 2z y + 1,z x  - t}, {t,z,y,x}]
      Type: List RegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [x,y,z,t],
      OrderedVariableList [x,y,z,t],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t]))
```

We can see that the first decomposition is a subset of the second.
So how can both be correct ?

Recall first that polynomials from a domain of the category
RecursivePolynomialCategory are regarded as univariate polynomials in
their main variable. For instance the second polynomial in the first
set of each decomposition has main variable y and its initial
(i.e. its leading coefficient w.r.t. its main variable) is t z.

Now let us explain how to read the second decomposition. Note that
the non-constant initials of the first set are t^4-t and $t z$. Then
the solutions described by this first set are the common zeros of
its polynomials that do not cancel the polynomials t^4-t and $ty z$.
Now the solutions of the input system lp satisfying these equations
are described by the second and the third sets of the decomposition.
Thus, in some sense, they can be considered as degenerated solutions.
The solutions given by the first set are called the generic points of
the system; they give the general form of the solutions. The first
decomposition only provides these generic points. This latter
decomposition is useful when there are many degenerated solutions
(which is sometimes hard to compute) and when one is only interested
in general informations, like the dimension of the input system.

We can get the dimensions of each component of a decomposition as follows.

```
[coHeight(ts) for ts in lts]
[1,0,0]
      Type: List NonNegativeInteger
```

Thus the first set has dimension one. Indeed t can take any value,
except 0 or any third root of 1, whereas z is completely determined
from t, y is given by z and t, and finally x is given by the other
three variables. In the second and the third sets of the second
decomposition the four variables are completely determined and thus
these sets have dimension zero.

We give now the precise specifications of each decomposition. This

assume some mathematical knowledge. However, for the non-expert user, the above explanations will be sufficient to understand the other features of the RSEGSET constructor.

The input system lp is decomposed in the sense of Kalkbrener as finitely many regular sets T_1, \dots, T_s such that the radical ideal generated by lp is the intersection of the radicals of the saturated ideals of T_1, \dots, T_s . In other words, the affine variety associated with lp is the union of the closures (w.r.t. Zarisky topology) of the regular-zeros sets of T_1, \dots, T_s .

N. B. The prime ideals associated with the radical of the saturated ideal of a regular triangular set have all the same dimension; moreover these prime ideals can be given by characteristic sets with the same main variables. Thus a decomposition in the sense of Kalkbrener is unmixed dimensional. Then it can be viewed as a lazy decomposition into prime ideals (some of these prime ideals being merged into unmixed dimensional ideals).

Now we explain the other way of solving by means of regular triangular sets. The input system lp is decomposed in the sense of Lazard as finitely many regular triangular sets T_1, \dots, T_s such that the affine variety associated with lp is the union of the regular-zeros sets of T_1, \dots, T_s . Thus a decomposition in the sense of Lazard is also a decomposition in the sense of Kalkbrener; the converse is false as we have seen before.

When the input system has a finite number of solutions, both ways of solving provide similar decompositions as we shall see with this second example (Caprasse).

Define a polynomial system.

```
f1 := y**2*z+2*x*y*t-2*x-z
      2
(2t y - 2)x + z y - z
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

f2:=-x**3*z+ 4*x*y**2*z+4*x**2*y*t+2*y**3*t+4*x**2-10*y**2+4*x*z-10*y*t+2
      3      2      2      3      2
- z x + (4t y + 4)x + (4z y + 4z)x + 2t y - 10y - 10t y + 2
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

f3 := 2*y*z*t+x*t**2-x-2*z
      2
(t - 1)x + 2t z y - 2z
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])
```

```
f4:=-x*z**3+4*y*z**2*t+4*x*z*t**2+2*y*t**3+4*x*z+4*z**2-10*y*t- 10*t**2+2
      3      2      2      3      2      2
      (- z  + (4t  + 4)z)x + (4t z  + 2t  - 10t)y + 4z  - 10t  + 2
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])
```

```
lf := [f1, f2, f3, f4]
      2
      [(2t y - 2)x + z y  - z,
      3      2      2      3      2
      - z x  + (4t y + 4)x  + (4z y  + 4z)x + 2t y  - 10y  - 10t y + 2,
      2
      (t  - 1)x + 2t z y - 2z,
      3      2      2      3      2      2
      (- z  + (4t  + 4)z)x + (4t z  + 2t  - 10t)y + 4z  - 10t  + 2]
      Type: List NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])
```

First of all, let us solve this system in the sense of Kalkbrener.

```
zeroSetSplit(lf)$T
      2      8      6      2      3      2
      [{t  - 1, z  - 16z  + 256z  - 256, t y - 1, (z  - 8z)x - 8z  + 16},
      2      2      2
      {3t  + 1, z  - 7t  - 1, y + t, x + z},
      8      6      2      3      2
      {t  - 10t  + 10t  - 1, z, (t  - 5t)y - 5t  + 1, x},
      2      2
      {t  + 3, z  - 4, y + t, x - z}]
      Type: List RegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [x,y,z,t],
      OrderedVariableList [x,y,z,t],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t]))
```

And now in the sense of Lazard (or Wu and other authors).

```
lts2 := zeroSetSplit(lf,false)$T
      8      6      2      3      2
      [{t  - 10t  + 10t  - 1, z, (t  - 5t)y - 5t  + 1, x},
      2      8      6      2      3      2
      {t  - 1, z  - 16z  + 256z  - 256, t y - 1, (z  - 8z)x - 8z  + 16},
      2      2      2      2      2
      {3t  + 1, z  - 7t  - 1, y + t, x + z}, {t  + 3, z  - 4, y + t, x - z}]
      Type: List RegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [x,y,z,t],
      OrderedVariableList [x,y,z,t],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t]))
```

Up to the ordering of the components, both decompositions are identical.

Let us check that each component has a finite number of solutions.

```
[coHeight(ts) for ts in lts2]
[0,0,0,0]
Type: List NonNegativeInteger
```

Let us count the degrees of each component,

```
degrees := [degree(ts) for ts in lts2]
[8,16,4,4]
Type: List NonNegativeInteger
```

and compute their sum.

```
reduce(+,degrees)
32
Type: PositiveInteger
```

We study now the options of the `zeroSetSplit` operation. As we have seen yet, there is an optional second argument which is a boolean value. If this value is true (this is the default) then the decomposition is computed in the sense of Kalkbrener, otherwise it is computed in the sense of Lazard.

There is a second boolean optional argument that can be used (in that case the first optional argument must be present). This second option allows you to get some information during the computations.

Therefore, we need to understand a little what is going on during the computations. An important feature of the algorithm is that the intermediate computations are managed in some sense like the processes of a Unix system. Indeed, each intermediate computation may generate other intermediate computations and the management of all these computations is a crucial task for the efficiency. Thus any intermediate computation may be suspended, killed or resumed, depending on algebraic considerations that determine priorities for these processes. The goal is of course to go as fast as possible towards the final decomposition which means to avoid as much as possible unnecessary computations.

To follow the computations, one needs to set to true the second argument. Then a lot of numbers and letters are displayed. Between a [and a] one has the state of the processes at a given time. Just after [one can see the number of processes. Then each process is represented by two numbers between < and >. A process consists of a list of polynomial `ps` and a triangular set `ts`; its goal is to compute the common zeros of `ps` that belong to the regular-zeros set of `ts`. After the processes, the number between pipes gives the total number

of polynomials in all the sets `ps`. Finally, the number between braces gives the number of components of a decomposition that are already computed. This number may decrease.

Let us take a third example (Czapor-Geddes-Wang) to see how this information is displayed.

Define a polynomial system.

```

u : R := 2
  2
                                     Type: Integer

]
Type: List NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

```

Let us try the information option. N.B. The timing should be between 1 and 10 minutes, depending on your machine.

```

```

Between a sequence of processes, thus between a] and a [you can see capital letters W, G, I and lower case letters i, w. Each time a capital letter appears a non-trivial computation has been performed and its result is put in a hash-table. Each time a lower case letter appears a needed result has been found in an hash-table. The use of these hash-tables generally speed up the computations. However, on very large systems, it may happen that these hash-tables become too big to be handle by your AXIOM configuration. Then in these exceptional cases, you may prefer getting a result (even if it takes a long time) than getting nothing. Hence you need to know how to prevent the RSEGET constructor from using these hash-tables. In that case you will be using the zeroSetSplit with five arguments. The first one is the input system lp as above. The second one is a boolean value hash? which is true iff you want to use hash-tables. The third one is boolean value clos? which is true iff you want to solve your system in the sense of Kalkbrener, the other way remaining that of Lazard. The fourth argument is boolean value info? which is true iff you want to display information during the computations. The last one is boolean value prep? which is true iff you want to use some heuristics that are performed on the input system before starting the real algorithm. The value of this flag is true when you are using zeroSetSplit with less than five arguments. Note that there is no available signature for zeroSetSplit with four arguments.

We finish this section by some remarks about both ways of solving, in the sense of Kalkbrener or in the sense of Lazard. For problems with a finite number of solutions, there are theoretically equivalent and the resulting decompositions are identical, up to the ordering of the components. However, when solving in the sense of Lazard, the

algorithm behaves differently. In that case, it becomes more incremental than in the sense of Kalkbrener. That means the polynomials of the input system are considered one after another whereas in the sense of Kalkbrener the input system is treated more globally.

This makes an important difference in positive dimension. Indeed when solving in the sense of Kalkbrener, the Primeidealkettensatz of Krull is used. That means any regular triangular containing more polynomials than the input system can be deleted. This is not possible when solving in the sense of Lazard. This explains why Kalkbrener's decompositions usually contain less components than those of Lazard. However, it may happen with some examples that the incremental process (that cannot be used when solving in the sense of Kalkbrener) provide a more efficient way of solving than the global one even if the Primeidealkettensatz is used. Thus just try both, with the various options, before concluding that you cannot solve your favorite system with `zeroSetSplit`. There exist more options at the development level that are not currently available in this public version.

```
=====
RewriteRule examples
=====
```

For example:

```
logrule := rule log(x) + log(y) == log(x*y)
          log(y) + log(x) + %C == log(x y) + %C

f := log(sin(x)) + log(x)
   log(sin(x)) + log(x)

logrule f
   log(x sin(x))
```

Note that you cannot write the simple form of a rule as:

```
rule1 := rule a*x+b == b*x+a
```

as this causes an infinite loop. The pattern is properly matched but the result also properly matches and the pattern is applied again.

domain ROIRC RightOpenIntervalRootCharacterization

The domain RightOpenIntervalRootCharacterization is the main code that provides the functionalities of RealRootCharacterizationCategory for the case of archimedean fields. Abstract roots are encoded with a left closed right open interval containing the root together with a defining polynomial for the root.

CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like $\sqrt{2} + \sqrt{2}$ you have two new variables which happen to be equal. To avoid this name the expression such as in $s2 := \sqrt{2}$; $s2 + s2$

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

LIMITATIONS

The file reclos.input show some basic use of the package. This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, inparticular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Betas versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

=====

RomanNumeral Examples

=====

The Roman numeral package was added to Axiom in MCMLXXXVI for use in denoting higher order derivatives.

For example, let f be a symbolic operator.

```

f := operator 'f
f

```

Type: BasicOperator

This is the seventh derivative of f with respect to x .

```

D(f x,x,7)
(vii)
f      (x)

```

Type: Expression Integer

You can have integers printed as Roman numerals by declaring variables to be of type RomanNumeral (abbreviation ROMAN).

```

a := roman(1978 - 1965)
XIII

```

Type: RomanNumeral

This package now has a small but devoted group of followers that claim this domain has shown its efficacy in many other contexts. They claim that Roman numerals are every bit as useful as ordinary integers.

In a sense, they are correct, because Roman numerals form a ring and you can therefore construct polynomials with Roman numeral coefficients, matrices over Roman numerals, etc..

```
x : UTS(ROMAN,'x,0) := x
x
Type: UnivariateTaylorSeries(RomanNumeral,x,0)
```

Was Fibonacci Italian or ROMAN?

```
recip(1 - x - x**2)
      2      3      4      5      6      7      8
      I + x + II x + III x + V x + VIII x + XIII x + XXI x + XXXIV x
+
      9      10      11
      LV x + LXXXIX x + O(x )
Type: Union(UnivariateTaylorSeries(RomanNumeral,x,0),...)
```

You can also construct fractions with Roman numeral numerators and denominators, as this matrix Hilberticus illustrates.

```
m : MATRIX FRAC ROMAN
Type: Void

m := matrix [ [1/(i + j) for i in 1..3] for j in 1..3]
      + I      I      I+
      |--    ---  --|
      |II     III  IV|
      |       |
      | I      I   I |
      |---   --   - |
      |III    IV   V |
      |       |
      | I      I   I |
      |--    -   --|
      +IV     V    VI+
Type: Matrix Fraction RomanNumeral
```

Note that the inverse of the matrix has integral ROMAN entries.

```
inverse m
      +LXXII   - CCXL   CLXXX +
      |         |
      |- CCXL   CM      - DCCXX|
      |         |
      +CLXXX   - DCCXX   DC      +
Type: Union(Matrix Fraction RomanNumeral,...)
```

Unfortunately, the spoil-sports say that the fun stops when the numbers get big---mostly because the Romans didn't establish conventions about representing very large numbers.

```
y := factorial 10
3628800
```

Type: PositiveInteger

You work it out!

```
roman y
(((I)))(((I)))(((I))) ((I))((I))((I))((I))((I))((I)) ((I))(
(I)) MMMMMMMDCCC
```

Type: RomanNumeral

Issue the system command `)show RomanNumeral` to display the full list of operations defined by RomanNumeral.

```
a := roman(78)
LXXVIII
```

Type: RomanNumeral

```
b := roman(87)
LXXXVII
```

Type: RomanNumeral

```
a + b
CLXV
```

Type: RomanNumeral

```
a * b
MMMMMDCCCLXXXVI
```

Type: RomanNumeral

```
b rem a
IX
```

Type: RomanNumeral

— domain ROMAN RomanNumeral —

```
)abbrev domain ROMAN RomanNumeral
++ Author: Mark Botch
++ Description:
```

```

++ \spadtype{RomanNumeral} provides functions for converting
++ integers to roman numerals.

RomanNumeral(): IntegerNumberSystem with
  canonical
  ++ mathematical equality is data structure equality.
  canonicalsClosed
  ++ two positives multiply to give positive.
  noetherian
  ++ ascending chain condition on ideals.
  convert: Symbol -> %
  ++ convert(n) creates a roman numeral for symbol n.
  roman : Symbol -> %
  ++ roman(n) creates a roman numeral for symbol n.
  roman : Integer -> %
  ++ roman(n) creates a roman numeral for n.

== Integer add
  import NumberFormats()

  roman(n:Integer) == n::%
  roman(sy:Symbol) == convert sy
  convert(sy:Symbol):% == ScanRoman(string sy)::%

  coerce(r:%):OutputForm ==
    n := convert(r)@Integer
    -- okay, we stretch it
    zero? n => n::OutputForm
    negative? n => -((-r)::OutputForm)
    FormatRoman(n::PositiveInteger)::Symbol::OutputForm

ScriptFormulaFormat examples
=====
```

ScriptFormulaFormat provides a coercion from OutputForm} to IBM SCRIPT/VS Mathematical Formula Format. The basic SCRIPT formula format object consists of three parts: a prologue, a formula part and an epilogue. The functions prologue, formula and epilogue extract these parts, respectively. The central parts of the expression go into the formula part. The other parts can be set (setPrologue!, setEpilogue!) so that contain the appropriate tags for printing. For example, the prologue and epilogue might simply contain ":df." and ":edf." so that the formula section will be printed in display math mode.

See Also:

=====

Segment examples

=====

The Segment domain provides a generalized interval type.

Segments are created using the .. construct by indicating the (included) end points.

```

s := 3..10
3..10
                                         Type: Segment PositiveInteger

```

The first end point is called the lo and the second is called hi.

```
lo s
  3
```

Type: PositiveInteger

These names are used even though the end points might belong to an unordered set.

```
hi s
  10
```

Type: PositiveInteger

In addition to the end points, each segment has an integer "increment". An increment can be specified using the "by" construct.

```
t := 10..3 by -2
    10..3 by - 2
```

Type: Segment PositiveInteger

This part can be obtained using the incr function.

```
incr s
  1
```

Type: PositiveInteger

Unless otherwise specified, the increment is 1.

```
incr t
  - 2
```

Type: Integer

A single value can be converted to a segment with equal end points. This happens if segments and single values are mixed in a list.

```
l := [1..3, 5, 9, 15..11 by -1]
     [1..3,5..5,9..9,15..11 by - 1]
```

Type: List Segment PositiveInteger

If the underlying type is an ordered ring, it is possible to perform additional operations. The expand operation creates a list of points in a segment.

```
expand s
  [3,4,5,6,7,8,9,10]
```

Type: List Integer

If $k > 0$, then `expand(l..h by k)` creates the list `[l, l+k, ..., lN]` where $lN \leq h < lN+k$. If $k < 0$, then $lN \geq h > lN+k$.

```
expand t
  [10,8,6,4]
```

Type: List Integer

It is also possible to expand a list of segments. This is equivalent to appending lists obtained by expanding each segment individually.

```
expand 1
  [1,2,3,5,9,15,14,13,12,11]
```

Type: List Integer

=====
SegmentBinding examples
=====

```

The SegmentBinding type is used to indicate a range for a named symbol.

First give the symbol, then an = and finally a segment of values.

```
x = a..b
x= a..b
```

Type: SegmentBinding Symbol

This is used to provide a convenient syntax for arguments to certain operations.

```
sum(i**2, i = 0..n)
      3      2
    2n  + 3n  + n
    -----
           6
```

Type: Fraction Polynomial Integer

```
draw(x**2, x = -2..2)
TwoDimensionalViewport: "x*x"
```

Type: TwoDimensionalViewport

The left-hand side must be of type Symbol but the right-hand side can be a segment over any type.

```
sb := y = 1/2..3/2
      1      3
    y= (-)..(-)
      2      2
```

Type: SegmentBinding Fraction Integer

The left- and right-hand sides can be obtained using the variable and segment operations.

```
variable(sb)
y
```

Type: Symbol

```
segment(sb)
      1      3
    (-)..(-)
      2      2
```

Type: Segment Fraction Integer

— domain SEGBIND SegmentBinding —

```

)abbrev domain SEGBIND SegmentBinding
++ Author: Mark Botch
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain is used to provide the function argument syntax \spad{v=a..b}.
++ This is used, for example, by the top-level \spadfun{draw} functions.

```

```

SegmentBinding(S:Type): Type with
  equation: (Symbol, Segment S) -> %
    ++ equation(v,a..b) creates a segment binding value with variable
    ++ \spad{v} and segment \spad{a..b}. Note that the interpreter parses
    ++ \spad{v=a..b} to this form.
  variable: % -> Symbol
    ++ variable(segb) returns the variable from the left hand side of
    ++ the \spadtype{SegmentBinding}. For example, if \spad{segb} is
    ++ \spad{v=a..b}, then \spad{variable(segb)} returns \spad{v}.
  segment : % -> Segment S
    ++ segment(segb) returns the segment from the right hand side of
    ++ the \spadtype{SegmentBinding}. For example, if \spad{segb} is
    ++ \spad{v=a..b}, then \spad{segment(segb)} returns \spad{a..b}.

Set examples

=====

The Set domain allows one to represent explicit finite sets of values. These are similar to lists, but duplicate elements are not allowed.

Sets can be created by giving a fixed set of values ...

```

s := set [x**2-1, y**2-1, z**2-1]
      2      2      2
      {x  - 1, y  - 1, z  - 1}
                                         Type: Set Polynomial Integer

```

or by using a collect form, just as for lists. In either case, the set is formed from a finite collection of values.

```

t := set [x**i - i+1 for i in 2..10 | prime? i]
      2      3      5      7
      {x  - 1, x  - 2, x  - 4, x  - 6}
                                         Type: Set Polynomial Integer

```

The basic operations on sets are intersect, union, difference, and symmetricDifference.

```

i := intersect(s,t)
      2
      {x  - 1}
                                         Type: Set Polynomial Integer

```

```

u := union(s,t)
      2      3      5      7      2      2
      {x  - 1, x  - 2, x  - 4, x  - 6, y  - 1, z  - 1}
                                         Type: Set Polynomial Integer

```

The set difference(s,t) contains those members of s which are not in t.

```

difference(s,t)
      2      2

```

```
{y - 1, z - 1}
```

```
Type: Set Polynomial Integer
```

The set `symmetricDifference(s,t)` contains those elements which are in `s` or `t` but not in both.

```
symmetricDifference(s,t)
```

```
      3      5      7      2      2
{x - 2, x - 4, x - 6, y - 1, z - 1}
```

```
Type: Set Polynomial Integer
```

Set membership is tested using the `member?` operation.

```
member?(y, s)
```

```
false
```

```
Type: Boolean
```

```
member?((y+1)*(y-1), s)
```

```
true
```

```
Type: Boolean
```

The `subset?` function determines whether one set is a subset of another.

```
subset?(i, s)
```

```
true
```

```
Type: Boolean
```

```
subset?(u, s)
```

```
false
```

```
Type: Boolean
```

When the base type is finite, the absolute complement of a set is defined. This finds the set of all multiplicative generators of `PrimeField 11`---the integers mod 11.

```
gs := set [g for i in 1..11 | primitive?(g := i::PF 11)]
{2,6,7,8}
```

```
Type: Set PrimeField 11
```

The following values are not generators.

```
complement gs
```

```
{1,3,4,5,9,10,0}
```

```
Type: Set PrimeField 11
```

Often the members of a set are computed individually; in addition, values can be inserted or removed from a set over the course of a computation.

There are two ways to do this:

```
a := set [i**2 for i in 1..5]
      {1,4,9,16,25}
                        Type: Set PositiveInteger
```

One is to view a set as a data structure and to apply updating operations.

```
insert!(32, a)
      {1,4,9,16,25,32}
                        Type: Set PositiveInteger
```

```
remove!(25, a)
      {1,4,9,16,32}
                        Type: Set PositiveInteger
```

```
a
      {1,4,9,16,32}
                        Type: Set PositiveInteger
```

The other way is to view a set as a mathematical entity and to create new sets from old.

```
b := b0 := set [i**2 for i in 1..5]
      {1,4,9,16,25}
                        Type: Set PositiveInteger
```

```
b := union(b, {32})
      {1,4,9,16,25,32}
                        Type: Set PositiveInteger
```

```
b := difference(b, {25})
      {1,4,9,16,32}
                        Type: Set PositiveInteger
```

```
b0
      {1,4,9,16,25}
                        Type: Set PositiveInteger
```

— domain SET Set —

```

)abbrev domain SET Set
++ Author: Michael Monagan; revised by Richard Jenks
++ Date Created: August 87 through August 88
++ Date Last Updated: May 1991
++ Description:
++ A set over a domain D models the usual mathematical notion of a finite set
++ of elements from D.
++ Sets are unordered collections of distinct elements
++ (that is, order and duplication does not matter).
++ The notation \spad{set [a,b,c]} can be used to create
++ a set and the usual operations such as union and intersection are available
++ to form new sets.
++ In our implementation, \Language{} maintains the entries in
++ sorted order. Specifically, the parts function returns the entries
++ as a list in ascending order and
++ the extract operation returns the maximum entry.
++ Given two sets s and t where \spad{#s = m} and \spad{#t = n},
++ the complexity of\br
++ \tab{5}\spad{s = t} is \spad{O(min(n,m))}\br
  
```

```

++ \tab{5}\spad{s < t} is \spad{0(max(n,m))}\br
++ \tab{5}\spad{union(s,t)}, \spad{intersect(s,t)}, \spad{minus(s,t)},\br
++ \tab{10 \spad{symmetricDifference(s,t)} is \spad{0(max(n,m))}\br
++ \tab{5}\spad{member(x,t)} is \spad{0(n log n)}\br
++ \tab{5}\spad{insert(x,t)} and \spad{remove(x,t)} is \spad{0(n)}

```

```

++ Date Created: 10 January 1994
++ Date Last Updated: 10 January 1994
++ Description:
++ \spadtype{SetOfMIntegersInOneToN} implements the subsets of M integers
++ in the interval \spad{[1..n]}

SetOfMIntegersInOneToN(m, n): Exports == Implementation where
  PI ==> PositiveInteger
  N ==> NonNegativeInteger
  U ==> Union(%, "failed")
  n,m: PI

Exports ==> Finite with
  incrementKthElement: (%, PI) -> U
    ++ incrementKthElement(S,k) increments the kth element of S,
    ++ and returns "failed" if the result is not a set of M integers
    ++ in \spad{[1..n]} any more.
  replaceKthElement: (%, PI, PI) -> U
    ++ replaceKthElement(S,k,p) replaces the kth element of S by p,
    ++ and returns "failed" if the result is not a set of M integers
    ++ in \spad{[1..n]} any more.
  elements: % -> List PI
    ++ elements(S) returns the list of the elements of S in increasing order.
  setOfMinN: List PI -> %
    ++ setOfMinN([a_1,...,a_m]) returns the set {a_1,...,a_m}.
    ++ Error if {a_1,...,a_m} is not a set of M integers in \spad{[1..n]}.
  enumerate: () -> Vector %
    ++ enumerate() returns a vector of all the sets of M integers in
    ++ \spad{[1..n]}.
  member?: (PI, %) -> Boolean
    ++ member?(p, s) returns true if p is in s, false otherwise.
  delta: (%, PI, PI) -> N
    ++ delta(S,k,p) returns the number of elements of S which are strictly
    ++ between p and the kth element of S.

Implementation ==> add

=====

SequentialDifferentialVariable examples

=====

OrderlyDifferentialVariable adds a commonly used sequential ranking to the set of derivatives of an ordered list of differential indeterminates. A sequential ranking is a ranking $<$ of the derivatives with the property that for any derivative v , there are only a finite number of derivatives u with $u < v$. This domain belongs to DifferentialVariableCategory. It defines weight to be just order, and it defines a sequential ranking $<$ on derivatives u by the lexicographic order on the pair $(\text{variable}(u), \text{order}(u))$.

SimpleAlgebraicExtension examples

Algebraic extension of a ring by a single polynomial. Domain which represents simple algebraic extensions of arbitrary rings. The first argument to the domain, R, is the underlying ring, the second argument is a domain of univariate polynomials over K, while the last argument specifies the defining minimal polynomial.

The elements of the domain are canonically represented as polynomials of degree less than that of the minimal polynomial with coefficients in R. The second argument is both the type of the third argument and the underlying representation used by SAE itself.

domain SINT SingleInteger

This type represents finite (machine) precision integers which wrap around at a machine dependent value. However, **SingleInteger** has type **EntireRing** which should have no non-zero divisors. But

$$(2 * 16 : SINT) ** 2 = 0$$

on a 32 bit machine. Using **SingleInteger** is a pragmatic efficiency choice. In this condition, Axiom will complain that the result is not of type FIXNUM, which is the Common Lisp type for machine integers.

=====
SingleInteger examples
=====

```

The SingleInteger domain is intended to provide support in Axiom for machine integer arithmetic. It is generally much faster than (bignum) Integer arithmetic but suffers from a limited range of values. Since Axiom can be implemented on top of various dialects of Lisp, the actual representation of small integers may not correspond exactly to the host machines integer representation.

You can discover the minimum and maximum values in your implementation

by using min and max.

```
min()$SingleInteger
- 2147483648
Type: SingleInteger
```

```
max()$SingleInteger
2147483647
Type: SingleInteger
```

To avoid confusion with Integer, which is the default type for integers, you usually need to work with declared variables.

```
a := 1234 :: SingleInteger
1234
Type: SingleInteger
```

or use package calling

```
b := 124$SingleInteger
124
Type: SingleInteger
```

You can add, multiply and subtract SingleInteger objects, and ask for the greatest common divisor (gcd).

```
gcd(a,b)
2
Type: SingleInteger
```

The least common multiple (lcm) is also available.

```
lcm(a,b)
76508
Type: SingleInteger
```

Operations mulmod, addmod, submod, and invmod are similar - they provide arithmetic modulo a given small integer.

Here is $5 * 6 \bmod 13$.

```
mulmod(5,6,13)$SingleInteger
4
Type: SingleInteger
```

To reduce a small integer modulo a prime, use positiveRemainder.

```
positiveRemainder(37,13)$SingleInteger
11
Type: SingleInteger
```

Operations And, Or, xor, and Not provide bit level operations on small integers.

```
And(3,4)$SingleInteger
0
```

Type: SingleInteger

Use shift(int,numToShift) to shift bits, where i is shifted left if numToShift is positive, right if negative.

```
shift(1,4)$SingleInteger
16
```

Type: SingleInteger

```
shift(31,-1)$SingleInteger
15
```

Type: SingleInteger

Many other operations are available for small integers, including many of those provided for Integer.

=====
SparseMultivariateTaylorSeries examples
=====

```

Assume we have three variables which get expressed as sparse multivariate taylor series.

```

xts:=x::TaylorSeries Fraction Integer
yts:=y::TaylorSeries Fraction Integer
zts:=z::TaylorSeries Fraction Integer

```

These will cause traditional routines to expand in series form:

```
t1:=sin(xts)
```

$$x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9 + O(11)$$

We can ask for a specific coefficient, in this case, the coefficient of the third power.

```
coefficient(t1,3)
```

$$-\frac{1}{6}x^3$$

And we can get that coefficient, expressed as a monomial.

```
coefficient(t1,monomial(3,x)$IndexedExponents Symbol)
```

$$-\frac{1}{6}$$

In a multivariate version we get a polynomial in x and y

```
t2:=sin(xts + yts)
```

$$\begin{aligned}
 & (y + x) + \left(-\frac{1}{6}y^3 - \frac{1}{2}xy^2 - \frac{1}{2}x^2y - \frac{1}{6}x^3 \right) \\
 & + \left(\frac{1}{120}y^5 + \frac{1}{24}xy^4 + \frac{1}{12}x^2y^3 + \frac{1}{12}x^3y^2 + \frac{1}{24}x^4y + \frac{1}{120}x^5 \right) \\
 & + \text{PAREN} \\
 & \quad -\frac{1}{5040}y^7 - \frac{1}{720}xy^6 - \frac{1}{240}x^2y^5 - \frac{1}{144}x^3y^4 - \frac{1}{144}x^4y^3 - \frac{1}{240}x^5y^2 \\
 & \quad -\frac{1}{720}x^6y - \frac{1}{5040}x^7 \\
 & + \text{PAREN} \\
 & \quad \frac{1}{362880}y^9 + \frac{1}{40320}xy^8 + \frac{1}{10080}x^2y^7 + \frac{1}{4320}x^3y^6 + \frac{1}{2880}x^4y^5 \\
 & \quad + \frac{1}{2880}x^5y^4 + \frac{1}{4320}x^6y^3 + \frac{1}{10080}x^7y^2 + \frac{1}{40320}x^8y + \frac{1}{362880}x^9 \\
 & + 0(11)
 \end{aligned}$$

We can ask for the third coefficient which is

```
coefficient(t2,3)
```

$$-\frac{1}{6}y^3 - \frac{1}{2}xy^2 - \frac{1}{2}x^2y - \frac{1}{6}x^3$$

And we can ask for the third coefficient of that coefficient in x

```
coefficient(t2,monomial(3,x)$IndexedExponents Symbol)
```

$$-\frac{1}{6}$$

And we can convert that result to a polynomial

polynomial(t2,5)

$$\begin{aligned} & \frac{1}{120} y^5 + \frac{1}{24} x y^4 + \left(-\frac{1}{12} x^2 - \frac{1}{6} \right) y^3 + \left(-\frac{1}{12} x^3 - \frac{1}{2} x \right) y^2 + \left(-\frac{1}{24} x^4 - \frac{1}{2} x^2 + 1 \right) y \\ & + \frac{1}{120} x^5 - \frac{1}{6} x^3 + x \end{aligned}$$

— domain SMTS SparseMultivariateTaylorSeries —

```
)abbrev domain SMTS SparseMultivariateTaylorSeries
++ Authors: William Burge, Stephen Watt, Clifton Williamson
++ Date Created: 15 August 1988
++ Date Last Updated: 18 May 1991
++ Description:
++ This domain provides multivariate Taylor series with variables
++ from an arbitrary ordered set. A Taylor series is represented
++ by a stream of polynomials from the polynomial domain SMP.
++ The nth element of the stream is a form of degree n. SMTS is an
++ internal domain.
```

```

=====
SparseTable examples
=====
```

```
t.3 := "Number three"
      "Number three"
                                     Type: String
```

```
t.4 := "Number four"
      "Number four"
```

Type: String

These values can be retrieved as usual, but if a look up fails the default entry will be returned.

```
t.3
      "Number three"
```

Type: String

```
t.2
      "Try again!"
```

Type: String

To see which values are explicitly stored, the keys and entries functions can be used.

```
keys t
      [4,3]
```

Type: List Integer

```
entries t
      ["Number four","Number three"]
```

Type: List String

If a specific table representation is required, the GeneralSparseTable constructor should be used. The domain SparseTable(K, E, dflt)} is equivalent to GeneralSparseTable(K,E,Table(K,E), dflt).

=====

SparseUnivariateLaurentSeries examples

=====

SparseUnivariateLaurentSeries is a domain representing Laurent series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, SparseUnivariateLaurentSeries(Integer,x,3) represents Laurent series in (x - 3) with integer coefficients.

SparseUnivariatePolynomial examples

=====

This domain represents univariate polynomials over arbitrary (not necessarily commutative) coefficient rings. The variable is unspecified so that the variable displays as ? on output. If it is necessary to specify the variable name, use type UnivariatePolynomial. The representation is sparse in the sense that only non-zero terms are represented. Note that if the coefficient ring is a field, this domain forms a euclidean domain.

)abbrev domain SUP SparseUnivariatePolynomial
++ Author: Dave Barton, Barry Trager
++ Description:
++ This domain represents univariate polynomials over arbitrary
++ (not necessarily commutative) coefficient rings. The variable is
++ unspecified so that the variable displays as \spad{?} on output.
++ If it is necessary to specify the variable name,
++ use type \spadtype{UnivariatePolynomial}. The representation is sparse
++ in the sense that only non-zero terms are represented.
++ Note that if the coefficient ring is a field,
++ this domain forms a euclidean domain.

SparseUnivariatePolynomial(R:Ring): UnivariatePolynomialCategory(R) with
  outputForm : (%,OutputForm) -> OutputForm
    ++ outputForm(p,var) converts the SparseUnivariatePolynomial p to
    ++ an output form (see \spadtype{OutputForm}) printed as a polynomial in the
    ++ output form variable.
  fmeq: (%,NonNegativeInteger,R,%) -> %
    ++ fmeq(p1,e,r,p2) finds x : p1 - r * x**e * p2

domain SUEXPR SparseUnivariatePolynomialExpressions

This domain is a hack, in some sense. What I'd really like to do - automatically - is to provide all operations supported by the coefficient domain, as long as the polynomials can be retracted to that domain, i.e., as long as they are just constants. I don't see another way to do this, unfortunately.

=====
SparseUnivariatePuisseuxSeries examples
=====

```

SparseUnivariatePuisseuxSeries is a domain representing Puiseux series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, SparseUnivariatePuisseuxSeries(Integer,x,3) represents Puiseux series in $(x - 3)$ with Integer coefficients.

=====
SparseUnivariateTaylorSeries examples
=====

```

SparseUnivariateTaylorSeries is a domain representing Taylor series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, `SparseUnivariateTaylorSeries(Integer,x,3)` represents Taylor series in $(x - 3)$ with Integer coefficients.

SplitHomogeneousDirectProduct examples

=====

This type represents the finite direct or cartesian product of an underlying ordered component type. The vectors are ordered as if they were split into two blocks. The `dim1` parameter specifies the length of the first block. The ordering is lexicographic between the blocks but acts like `HomogeneousDirectProduct` within each block. This type is a suitable third argument for `GeneralDistributedMultivariatePolynomial`.

SplittingNode examples

=====

This domain exports a modest implementation for the vertices of splitting trees. These vertices are called here splitting nodes. Every of these nodes store 3 informations. The first one is its value, that is the current expression to evaluate. The second one is its condition, that is the hypothesis under which the value has to be evaluated. The last one is its status, that is a boolean flag which is true iff the value is the result of its evaluation under its condition. Two splitting vertices are equal iff they have the same values and the same conditions (so their status do not matter).

=====

SplittingTree examples

=====

This domain exports a modest implementation of splitting trees. Splitting trees are needed when the evaluation of some quantity under some hypothesis requires to split the hypothesis into sub-cases. For instance by adding some new hypothesis on one hand and its negation on another hand. The computations are terminated is a splitting tree *a* when `status(value(a))` is true. Thus, if for the splitting tree *a* the flag `status(value(a))` is true, then `status(value(d))` is true for any subtree *d* of *a*. This property of splitting trees is called the termination condition. If no vertex in a splitting tree *a* is equal to another, *a* is said to satisfy the no-duplicates condition. The splitting tree *a* will satisfy this condition if nodes are added to *a* by mean of `splitNodeOf!` and if `construct` is only used to create the root of *a* with no children.

```

)abbrev domain SPLTREE SplittingTree
++ Author: Marc Moereno Maza
++ Date Created: 07/05/1996
++ Date Last Updated: 07/19/1996
++ References:
++   M. MORENO MAZA "Calculs de pgcd au-dessus des tours
++   d'extensions simples et resolution des systemes d'equations
++   algebriques" These, Universite P.etM. Curie, Paris, 1997.
++ Description:
++ This domain exports a modest implementation of splitting
++ trees. Splitting trees are needed when the
++ evaluation of some quantity under some hypothesis
++ requires to split the hypothesis into sub-cases.
++ For instance by adding some new hypothesis on one
++ hand and its negation on another hand. The computations
++ are terminated is a splitting tree \axiom{a} when
  
```

```

++ \axiom{status(value(a))} is \axiom{true}. Thus,
++ if for the splitting tree \axiom{a} the flag
++ \axiom{status(value(a))} is \axiom{true}, then
++ \axiom{status(value(d))} is \axiom{true} for any
++ subtree \axiom{d} of \axiom{a}. This property
++ of splitting trees is called the termination
++ condition. If no vertex in a splitting tree \axiom{a}
++ is equal to another, \axiom{a} is said to satisfy
++ the no-duplicates condition. The splitting
++ tree \axiom{a} will satisfy this condition
++ if nodes are added to \axiom{a} by mean of
++ \axiom{splitNodeOf!} and if \axiom{construct}
++ is only used to create the root of \axiom{a}
++ with no children.

```

Exports == RecursiveAggregate(S) with
  shallowlyMutable
  finiteAggregate
  extractSplittingLeaf : % -> Union(%, "failed")
    ++ \axiom{extractSplittingLeaf(a)} returns the left
    ++ most leaf (as a tree) whose status is false
    ++ if any, else "failed" is returned.
  updateStatus! : % -> %
    ++ \axiom{updateStatus!(a)} returns a where the status
    ++ of the vertices are updated to satisfy
    ++ the "termination condition".
  construct : S -> %
    ++ \axiom{construct(s)} creates a splitting tree
    ++ with value (i.e. root vertex) given by
    ++ \axiom{s} and no children. Thus, if the
    ++ status of \axiom{s} is false, \axiom{[s]}
    ++ represents the starting point of the
    ++ evaluation \axiom{value(s)} under the
    ++ hypothesis \axiom{condition(s)}.
  construct : (V,C, List %) -> %
    ++ \axiom{construct(v,t,la)} creates a splitting tree
    ++ with value (i.e. root vertex) given by
    ++ \axiom{[v,t]$S} and with \axiom{la} as

```

```

++ children list.
construct : (V,C,List S) -> %
++ \axiom{construct(v,t,ls)} creates a splitting tree
++ with value (i.e. root vertex) given by
++ \axiom{[v,t]$S} and with children list given by
++ \axiom{[[s]$% for s in ls]}.
construct : (V,C,V,List C) -> %
++ \axiom{construct(v1,t,v2,lt)} creates a splitting tree
++ with value (i.e. root vertex) given by
++ \axiom{[v,t]$S} and with children list given by
++ \axiom{[[[v,t]$S]$% for s in ls]}.
conditions : % -> List C
++ \axiom{conditions(a)} returns the list of the conditions
++ of the leaves of a
result : % -> List VT
++ \axiom{result(a)} where \axiom{ls} is the leaves list of \axiom{a}
++ returns \axiom{[[value(s),condition(s)]$VT for s in ls]}
++ if the computations are terminated in \axiom{a} else
++ an error is produced.
nodeOf? : (S,%) -> B
++ \axiom{nodeOf?(s,a)} returns true iff some node of \axiom{a}
++ is equal to \axiom{s}
subNodeOf? : (S,%,(C,C) -> B) -> B
++ \axiom{subNodeOf?(s,a,sub?) } returns true iff for some node
++ \axiom{n} in \axiom{a} we have \axiom{s = n} or
++ \axiom{status(n)} and \axiom{subNode?(s,n,sub?)}.
remove : (S,%) -> %
++ \axiom{remove(s,a)} returns the splitting tree obtained
++ from a by removing every sub-tree \axiom{b} such
++ that \axiom{value(b)} and \axiom{s} have the same
++ value, condition and status.
remove! : (S,%) -> %
++ \axiom{remove!(s,a)} replaces a by remove(s,a)
splitNodeOf! : (%,%,List(S)) -> %
++ \axiom{splitNodeOf!(l,a,ls)} returns \axiom{a} where the children
++ list of \axiom{l} has been set to
++ \axiom{[[s]$% for s in ls | not nodeOf?(s,a)]}.
++ Thus, if \axiom{l} is not a node of \axiom{a}, this
++ latter splitting tree is unchanged.
splitNodeOf! : (%,%,List(S),(C,C) -> B) -> %
++ \axiom{splitNodeOf!(l,a,ls,sub?) } returns \axiom{a} where the children
++ list of \axiom{l} has been set to
++ \axiom{[[s]$% for s in ls | not subNodeOf?(s,a,sub?)}.
++ Thus, if \axiom{l} is not a node of \axiom{a}, this
++ latter splitting tree is unchanged.

=====

SquareFreeRegularTriangularSet examples

=====

The SquareFreeRegularTriangularSet domain constructor implements square-free regular triangular sets. See the RegularTriangularSet domain constructor for general regular triangular sets. Let T be a regular triangular set consisting of polynomials t1, ..., tm ordered by increasing main variables. The regular triangular set T is square-free if T is empty or if t1, ..., tm-1 is square-free and if the polynomial tm is square-free as a univariate polynomial with coefficients in the tower of simple extensions associated with t1,...,tm-1.

The main interest of square-free regular triangular sets is that their associated towers of simple extensions are product of fields. Consequently, the saturated ideal of a square-free regular triangular set is radical. This property simplifies some of the operations related to regular triangular sets. However, building square-free

regular triangular sets is generally more expensive than building general regular triangular sets.

As the `RegularTriangularSet` domain constructor, the `SquareFreeRegularTriangularSet` domain constructor also implements a method for solving polynomial systems by means of regular triangular sets. This is in fact the same method with some adaptations to take into account the fact that the computed regular chains are square-free. Note that it is also possible to pass from a decomposition into general regular triangular sets to a decomposition into square-free regular triangular sets. This conversion is used internally by the `LazardSetSolvingPackage` package constructor.

N.B. When solving polynomial systems with the `SquareFreeRegularTriangularSet` domain constructor or the `LazardSetSolvingPackage` package constructor, decompositions have no redundant components. See also `LexTriangularPackage` and `ZeroDimensionalSolvePackage` for the case of algebraic systems with a finite number of (complex) solutions.

We shall explain now how to use the constructor `SquareFreeRegularTriangularSet`.

This constructor takes four arguments. The first one, `R`, is the coefficient ring of the polynomials; it must belong to the category `GcdDomain`. The second one, `E`, is the exponent monoid of the polynomials; it must belong to the category `OrderedAbelianMonoidSup`. The third one, `V`, is the ordered set of variables; it must belong to the category `OrderedSet`. The last one is the polynomial ring; it must belong to the category `RecursivePolynomialCategory(R,E,V)`. The abbreviation for `SquareFreeRegularTriangularSet` is `SREGSET`.

Note that the way of understanding triangular decompositions is detailed in the example of the `RegularTriangularSet` constructor.

Let us illustrate the use of this constructor with one example (Donati-Traverso). Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the list of variables,

```
ls : List Symbol := [x,y,z,t]
[x,y,z,t]
Type: List Symbol
```

and make it an ordered set;

```
V := OVAR(ls)
```

```

OrderedVariableList [x,y,z,t]
                                Type: Domain

then define the exponent monoid.

E := IndexedExponents V
IndexedExponents OrderedVariableList [x,y,z,t]
                                Type: Domain

Define the polynomial ring.

P := NSMP(R, V)
NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])
                                Type: Domain

Let the variables be polynomial.

x: P := 'x
x
                                Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [x,y,z,t])

y: P := 'y
y
                                Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [x,y,z,t])

z: P := 'z
z
                                Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [x,y,z,t])

t: P := 't
t
                                Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [x,y,z,t])

Now call the SquareFreeRegularTriangularSet domain constructor.

ST := SREGSET(R,E,V,P)
SquareFreeRegularTriangularSet(Integer,IndexedExponents OrderedVariableList [
x,y,z,t],OrderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Intege
r,OrderedVariableList [x,y,z,t]))
                                Type: Domain

Define a polynomial system.

p1 := x ** 31 - x ** 6 - x - y
      31      6
      x  - x  - x - y

```

```

Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

p2 := x ** 8 - z
      8
      x - z
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

p3 := x ** 10 - t
      10
      x - t
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

lp := [p1, p2, p3]
      31      6      8      10
[x - x - x - y, x - z, x - t]
Type: List NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

```

First of all, let us solve this system in the sense of Kalkbrener.

```

zeroSetSplit(lp)$ST
      5      4      2      3      8      5      3      2      4      2
[{z - t , t z y + 2z y - t + 2t + t - t , (t - t)x - t y - z },
Type: List SquareFreeRegularTriangularSet(Integer,
IndexedExponents OrderedVariableList [x,y,z,t],
OrderedVariableList [x,y,z,t],
NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t]))

```

And now in the sense of Lazard (or Wu and other authors).

```

zeroSetSplit(lp,false)$ST
      5      4      2      3      8      5      3      2      4      2
[{z - t , t z y + 2z y - t + 2t + t - t , (t - t)x - t y - z },
      3      5      2      2
{t - 1, z - t, t y + z , z x - t}, {t,z,y,x}]
Type: List SquareFreeRegularTriangularSet(Integer,
IndexedExponents OrderedVariableList [x,y,z,t],
OrderedVariableList [x,y,z,t],
NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t]))

```

Now to see the difference with the RegularTriangularSet domain constructor, we define:

```

T := REGSET(R,E,V,P)
RegularTriangularSet(Integer,IndexedExponents OrderedVariableList [x,y,z,t],0

```

```

rderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,OrderedV
variableList [x,y,z,t]))

```

Type: Domain

and compute:

```

lts := zeroSetSplit(lp,false)$T
      5      4      2      3      8      5      3      2      4      2
      [z  - t ,t z y  + 2z y - t  + 2t  + t  - t ,(t  - t)x - t y - z },
      3      5      2      3      2
      {t  - 1,z  - t,t z y  + 2z y + 1,z x  - t}, {t,z,y,x}]
      Type: List RegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [x,y,z,t],
      OrderedVariableList [x,y,z,t],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t]))

```

If you look at the second set in both decompositions in the sense of Lazard, you will see that the polynomial with main variable y is not the same.

Let us understand what has happened.

We define:

```

ts := lts.2
      3      5      2      3      2
(19) {t  - 1,z  - t,t z y  + 2z y + 1,z x  - t}
      Type: RegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [x,y,z,t],
      OrderedVariableList [x,y,z,t],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t]))

pol := select(ts,'y)$T
      2      3
      t z y  + 2z y + 1
      Type: Union(NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t]),...)

tower := collectUnder(ts,'y)$T
      3      5
      {t  - 1,z  - t}
      Type: RegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [x,y,z,t],
      OrderedVariableList [x,y,z,t],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t]))

pack := RegularTriangularSetGcdPackage(R,E,V,P,T)
RegularTriangularSetGcdPackage(Integer,IndexedExponents OrderedVariableList [

```

```

x,y,z,t],OrderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t]),RegularTriangularSet(Integer,IndexedExponents
OrderedVariableList [x,y,z,t],OrderedVariableList [x,y,z,t],NewSparseMultiv
ariatePolynomial(Integer,OrderedVariableList [x,y,z,t])))
Type: Domain

```

Then we compute:

```

toseSquareFreePart(pol,tower)$pack
      2      3      5
[[val= t y + z ,tower= {t - 1,z - t}]]
Type: List Record(val: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t]),
tower: RegularTriangularSet(Integer,
IndexedExponents OrderedVariableList [x,y,z,t],
OrderedVariableList [x,y,z,t],
NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])))

```

— SquareMatrix.help —

SquareMatrix examples

The top level matrix type in Axiom is `Matrix`, which provides basic arithmetic and linear algebra functions. However, since the matrices can be of any size it is not true that any pair can be added or multiplied. Thus `Matrix` has little algebraic structure.

Sometimes you want to use matrices as coefficients for polynomials or in other algebraic contexts. In this case, `SquareMatrix` should be

used. The domain `SquareMatrix(n,R)` gives the ring of n by n square matrices over R .

Since `SquareMatrix` is not normally exposed at the top level, you must expose it before it can be used.

```
)set expose add constructor SquareMatrix
```

Once `SQMATRIX` has been exposed, values can be created using the `squareMatrix` function.

```
m := squareMatrix [ [1,-%i],[%i,4] ]
+1 - %i+
|      |
+%i  4  +
                                         Type: SquareMatrix(2,Complex Integer)
```

The usual arithmetic operations are available.

```
m*m - m
+ 1 - 4%i+
|      |
+4%i  13 +
                                         Type: SquareMatrix(2,Complex Integer)
```

Square matrices can be used where ring elements are required. For example, here is a matrix with matrix entries.

```
mm := squareMatrix [ [m, 1], [1-m, m**2] ]
++1 - %i+ +1 0+ +
||      | |  |  |
|+%i  4  + +0 1+ |
|      | |  |  |
|+ 0 %i + + 2 - 5%i+|
||      | |  ||  ||
++- %i - 3+ +5%i 17 ++
                                         Type: SquareMatrix(2,SquareMatrix(2,Complex Integer))
```

Or you can construct a polynomial with square matrix coefficients.

```
p := (x + m)**2
  2 + 2 - 2%i+ + 2 - 5%i+
x + |      |x + |      |
    +2%i  8  + +5%i 17  +
                                         Type: Polynomial SquareMatrix(2,Complex Integer)
```

This value can be converted to a square matrix with polynomial coefficients.

```
p::SquareMatrix(2, ?)
+ 2      +
```

```
|x  + 2x + 2  - 2%i x - 5%i|
|                               |
|               2             |
+2%i x + 5%i  x  + 8x + 17 +
                                Type: SquareMatrix(2,Polynomial Complex Integer)

)abbrev domain SQMATRIX SquareMatrix
++ Author: Grabmeier, Gschnitzer, Williamson
++ Date Created: 1987
++ Date Last Updated: July 1990
++ Description:
++ \spadtype{SquareMatrix} is a matrix domain of square matrices, where the
++ number of rows (= number of columns) is a parameter of the type.

SquareMatrix(ndim,R): Exports == Implementation where
  ndim : NonNegativeInteger
  R    : Ring
  Row ==> DirectProduct(ndim,R)
  Col ==> DirectProduct(ndim,R)
  MATLIN ==> MatrixLinearAlgebraFunctions(R,Row,Col,$)

Exports ==> Join(SquareMatrixCategory(ndim,R,Row,Col),_
  CoercibleTo Matrix R) with

  transpose: $ -> $
    ++ \spad{transpose(m)} returns the transpose of the matrix m.
  squareMatrix: Matrix R -> $
    ++ \spad{squareMatrix(m)} converts a matrix of type \spadtype{Matrix}
    ++ to a matrix of type \spadtype{SquareMatrix}.
  coerce: $ -> Matrix R
    ++ \spad{coerce(m)} converts a matrix of type \spadtype{SquareMatrix}
    ++ to a matrix of type \spadtype{Matrix}.
-- symdecomp : $ -> Record(sym:$,antisym:$)
-- ++ \spad{symdecomp(m)} decomposes the matrix m as a sum of a symmetric
-- ++ matrix \spad{m1} and an antisymmetric matrix \spad{m2}. The object
-- ++ returned is the Record \spad{[m1,m2]}

```

```

-- if R has commutative("*") then
--   minorsVect: -> Vector(Union(R,"uncomputed")) --range: 1..2**n-1
--   ++ \spad{minorsVect(m)} returns a vector of the minors of the matrix m
if R has commutative("*") then central
  ++ the elements of the Ring R, viewed as diagonal matrices, commute
  ++ with all matrices and, indeed, are the only matrices which commute
  ++ with all matrices.
if R has commutative("*") and R has unitsKnown then unitsKnown
  ++ the invertible matrices are simply the matrices whose determinants
  ++ are units in the Ring R.
if R has ConvertibleTo InputForm then ConvertibleTo InputForm

=====

Stack examples

=====

A Stack object is represented as a list ordered by last-in, first-out. It operates like a pile of books, where the "next" book is the one on the top of the pile.

Here we create a stack of integers from a list. Notice that the order in the list is the order in the stack.

```

a:Stack INT:= stack [1,2,3,4,5]
[1,2,3,4,5]

```

We can remove the top of the stack using pop!:

```

pop! a
1

```

Notice that the use of pop! is destructive (destructive operations in Axiom usually end with ! to indicate that the underlying data

structure is changed).

```
a
  [2,3,4,5]
```

The `extract!` operation is another name for the `pop!` operation and has the same effect. This operation treats the stack as a `BagAggregate`:

```
extract! a
  2
```

and you can see that it also has destructively modified the stack:

```
a
  [3,4,5]
```

Next we push a new element on top of the stack:

```
push!(9,a)
  9
```

Again, the `push!` operation is destructive so the stack is changed:

```
a
  [9,2,3,4,5]
```

Another name for `push!` is `insert!`, which treats the stack as a `BagAggregate`:

```
insert!(8,a)
  [8,9,3,4,5]
```

and it modifies the stack:

```
a
  [8,9,3,4,5]
```

The `inspect` function returns the top of the stack without modification, viewed as a `BagAggregate`:

```
inspect a
  8
```

The `empty?` operation returns `true` only if there are no element on the stack, otherwise it returns `false`:

```
empty? a
  false
```

The `top` operation returns the top of stack without modification, viewed as a `Stack`:

```
top a
8
```

The depth operation returns the number of elements on the stack:

```
depth a
5
```

which is the same as the # (length) operation:

```
#a
5
```

The less? predicate will compare the stack length to an integer:

```
less?(a,9)
true
```

The more? predicate will compare the stack length to an integer:

```
more?(a,9)
false
```

The size? operation will compare the stack length to an integer:

```
size?(a,#a)
true
```

and since the last computation must always be true we try:

```
size?(a,9)
false
```

The parts function will return the stack as a list of its elements:

```
parts a
[8,9,3,4,5]
```

If we have a BagAggregate of elements we can use it to construct a stack. Notice that the elements are pushed in reverse order:

```
bag([1,2,3,4,5])$Stack(INT)
[5,4,3,2,1]
```

The empty function will construct an empty stack of a given type:

```
b:=empty()$(Stack INT)
[]
```

and the empty? predicate allows us to find out if a stack is empty:

```
empty? b
true
```

The sample function returns a sample, empty stack:

```
sample()$Stack(INT)
[]
```

We can copy a stack and it does not share storage so subsequent modifications of the original stack will not affect the copy:

```
c:=copy a
[8,9,3,4,5]
```

The eq? function is only true if the lists are the same reference, so even though c is a copy of a, they are not the same:

```
eq?(a,c)
false
```

However, a clearly shares a reference with itself:

```
eq?(a,a)
true
```

But we can compare a and c for equality:

```
(a=c)@Boolean
true
```

and clearly a is equal to itself:

```
(a=a)@Boolean
true
```

and since a and c are equal, they are clearly NOT not-equal:

```
a~=c
false
```

We can use the any? function to see if a predicate is true for any element:

```
any?(x+>(x=4),a)
true
```

or false for every element:

```
any?(x+>(x=11),a)
```

```
false
```

We can use the `every?` function to check every element satisfies a predicate:

```
every?(x+>(x=11),a)
false
```

We can count the elements that are equal to an argument of this type:

```
count(4,a)
1
```

or we can count against a boolean function:

```
count(x+>(x>2),a)
5
```

You can also map a function over every element, returning a new stack:

```
map(x+>x+10,a)
[18,19,13,14,15]
```

Notice that the original stack is unchanged:

```
a
[8,9,3,4,5]
```

You can use `map!` to map a function over every element and change the original stack since `map!` is destructive:

```
map!(x+>x+10,a)
[18,19,13,14,15]
```

Notice that the original stack has been changed:

```
a
[18,19,13,14,15]
```

The `member` function can also get the element of the stack as a list:

```
members a
[18,19,13,14,15]
```

and using `member?` we can test if the stack holds a given element:

```
member?(14,a)
true
```

StochasticDifferential examples

=====

A basic implementation of StochasticDifferential(R) using the associated domain BasicStochasticDifferential in the underlying representation as sparse multivariate polynomials. The domain is a module over Expression(R), and is a ring without identity (AXIOM term is "Rng"). Note that separate instances, for example using R=Integer and R=Float, have different hidden structure (multiplication and drift tables).

```

dt := introduce!(t,dt)
dt

```

```

dX := introduce!(X,dX)
dX

```

```

dY := introduce!(Y,dY)
dY

```

```

— domain SD StochasticDifferential —

```

)abbrev domain SD StochasticDifferential
++ Author: Wilfrid S. Kendall
++ Last Last Updated: July 26, 1999
++ Related Domains: BasicStochasticDifferential

```

```

++ References: Ito (1975), Kendall (1991a,b; 1993a,b).
++ Description:
++ A basic implementation of StochasticDifferential(R) using the
++ associated domain BasicStochasticDifferential in the underlying
++ representation as sparse multivariate polynomials. The domain is
++ a module over Expression(R), and is a ring without identity
++ (AXIOM term is "Rng"). Note that separate instances, for example
++ using R=Integer and R=Float, have different hidden structure
++ (multiplication and drift tables).

```

```

StochasticDifferential(R:Join(OrderedSet, IntegralDomain)):

=====
Stream examples
=====

```

A Stream object is represented as a list whose last element contains the wherewithal to create the next element, should it ever be required.

Let ints be the infinite stream of non-negative integers.

```
ints := [i for i in 0..]
      [0,1,2,3,4,5,6,7,8,9,...]
                                     Type: Stream NonNegativeInteger
```

By default, ten stream elements are calculated. This number may be changed to something else by the system command
`)set streams calculate`

More generally, you can construct a stream by specifying its initial value and a function which, when given an element, creates the next element.

```
f : List INT -> List INT
                                     Type: Void

f x == [x.1 + x.2, x.1]
                                     Type: Void

fibs := [i.2 for i in [generate(f,[1,1])]]
      [1,1,2,3,5,8,13,21,34,55,...]
                                     Type: Stream Integer
```

You can create the stream of odd non-negative integers by either filtering them from the integers, or by evaluating an expression for each integer.

```
[i for i in ints | odd? i]
      [1,3,5,7,9,11,13,15,17,19,...]
                                     Type: Stream NonNegativeInteger

odds := [2*i+1 for i in ints]
      [1,3,5,7,9,11,13,15,17,19,...]
                                     Type: Stream NonNegativeInteger
```

You can accumulate the initial segments of a stream using the scan operation.

```
scan(0,+,odds)
      [1,4,9,16,25,36,49,64,81,100,...]
                                     Type: Stream NonNegativeInteger
```

The corresponding elements of two or more streams can be combined in this way.

```
[i*j for i in ints for j in odds]
      [0,3,10,21,36,55,78,105,136,171,...]
                                     Type: Stream NonNegativeInteger

map(*,ints,odds)
      [0,3,10,21,36,55,78,105,136,171,...]
                                     Type: Stream NonNegativeInteger
```

Many operations similar to those applicable to lists are available for

```
streams.  
  
  first ints  
    0  
                                     Type: NonNegativeInteger  
  
  rest ints  
    [1,2,3,4,5,6,7,8,9,10,...]  
                                     Type: Stream NonNegativeInteger  
  
  fibs 20  
    6765  
                                     Type: PositiveInteger
```

— domain **STREAM** Stream —

```

)abbrev domain STREAM Stream
++ Implementation of streams via lazy evaluation
++ Authors: Burge, Watt; updated by Clifton J. Williamson
++ Date Created: July 1986
++ Date Last Updated: 30 March 1990
++ Description:
++ A stream is an implementation of an infinite sequence using
++ a list of terms that have been computed and a function closure

```

```

++ to compute additional terms when needed.

Stream(S): Exports == Implementation where
-- problems:
-- 1) dealing with functions which basically want a finite structure
-- 2) 'map' doesn't deal with cycles very well

S : Type
B  ==> Boolean
OUT ==> OutputForm
I  ==> Integer
L  ==> List
NNI ==> NonNegativeInteger
U  ==> UniversalSegment I

Exports ==> LazyStreamAggregate(S) with
  shallowlyMutable
  ++ one may destructively alter a stream by assigning new
  ++ values to its entries.

coerce: L S -> %
  ++ coerce(l) converts a list l to a stream.
  ++
  ++X m:=[1,2,3,4,5,6,7,8,9,10,11,12]
  ++X coerce(m)@Stream(Integer)
  ++X m::Stream(Integer)

repeating: L S -> %
  ++ repeating(l) is a repeating stream whose period is the list l.
  ++
  ++X m:=repeating([-1,0,1,2,3])

if S has SetCategory then
  repeating?: (L S,% ) -> B
  ++ repeating?(l,s) returns true if a stream s is periodic
  ++ with period l, and false otherwise.
  ++
  ++X m:=[1,2,3]
  ++X n:=repeating(m)
  ++X repeating?(m,n)

findCycle: (NNI,% ) -> Record(cycle?: B, prefix: NNI, period: NNI)
  ++ findCycle(n,st) determines if st is periodic within n.
  ++
  ++X m:=[1,2,3]
  ++X n:=repeating(m)
  ++X findCycle(3,n)
  ++X findCycle(2,n)

delay: (( ) -> % ) -> %

```

```

++ delay(f) creates a stream with a lazy evaluation defined by
++ function f.
++ Caution: This function can only be called in compiled code.
cons: (S,%) -> %
++ cons(a,s) returns a stream whose \spad{first} is \spad{a}
++ and whose \spad{rest} is s.
++ Note: \spad{cons(a,s) = concat(a,s)}.
++
++X m:=[1,2,3]
++X n:=repeating(m)
++X cons(4,n)

if S has SetCategory then
output: (I, %) -> Void
++ output(n,st) computes and displays the first n entries
++ of st.
++
++X m:=[1,2,3]
++X n:=repeating(m)
++X output(5,n)

showAllElements: % -> OUT
++ showAllElements(s) creates an output form which displays all
++ computed elements.
++
++X m:=[1,2,3,4,5,6,7,8,9,10,11,12]
++X n:=m::Stream(PositiveInteger)
++X showAllElements n

showAll?: () -> B
++ showAll?() returns true if all computed entries of streams
++ will be displayed.
--!! this should be a function of one argument
setrest_!: (%I,%) -> %
++ setrest!(x,n,y) sets rest(x,n) to y. The function will expand
++ cycles if necessary.
++
++X p:=[i for i in 1..]
++X q:=[i for i in 9..]
++X setrest!(p,4,q)
++X p

generate: ((() -> S) -> %
++ generate(f) creates an infinite stream all of whose elements are
++ equal to \spad{f()}.
++ Note: \spad{generate(f) = [f(),f(),f(),...]}
++
++X f():Integer == 1
++X generate(f)

```

```

generate: (S -> S,S) -> %
++ generate(f,x) creates an infinite stream whose first element is
++ x and whose nth element (\spad{n > 1}) is f applied to the previous
++ element. Note: \spad{generate(f,x) = [x,f(x),f(f(x)),...]}
++
++X f(x:Integer):Integer == x+10
++X generate(f,10)

filterWhile: (S -> Boolean,%) -> %
++ filterWhile(p,s) returns \spad{[x0,x1,...,x(n-1)]} where
++ \spad{s = [x0,x1,x2,...]} and

=====
String examples
=====

```

The type `String` provides character strings. Character strings provide all the operations for a one-dimensional array of characters, plus additional operations for manipulating text.

String values can be created using double quotes.

```
hello := "Hello, I'm AXIOM!"
      "Hello, I'm AXIOM!"
                                     Type: String
```

Note, however, that double quotes and underscores must be preceded by an extra underscore.

```
said := "Jane said, \"Look!\""
      "Jane said, \"Look!\""
                                     Type: String
```

```
saw := "She saw exactly one underscore: \"_\"."
      "She saw exactly one underscore: \"_\"."
                                     Type: String
```

It is also possible to use `new` to create a string of any size filled with a given character. Since there are many new functions it is necessary to indicate the desired type.

```
gasp: String := new(32, char "x")
      "xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
                                     Type: String
```

The length of a string is given by `#`.

```
#gasp
32
                                     Type: PositiveInteger
```

Indexing operations allow characters to be extracted or replaced in strings. For any string `s`, indices lie in the range `1..#s`.

```
hello.2
e
                                     Type: Character
```

Indexing is really just the application of a string to a subscript, so any application syntax works.

```
hello 2
e
                                     Type: Character
```

```
hello(2)
e
Type: Character
```

If it is important not to modify a given string, it should be copied before any updating operations are used.

```
hullo := copy hello
"Hello, I'm AXIOM!"
Type: String
```

```
hullo.2 := char "u"; [hello, hullo]
["Hello, I'm AXIOM!", "Hullo, I'm AXIOM!"]
Type: List String
```

Operations are provided to split and join strings. The concat operation allows several strings to be joined together.

```
said saw := concat ["alpha", "---", "omega"]
"alpha---omega"
Type: String
```

There is a version of concat that works with two strings.

```
concat("hello ", "goodbye")
"hello goodbye"
Type: String
```

Juxtaposition can also be used to concatenate strings.

```
"This " "is " "several " "strings " "concatenated."
"This is several strings concatenated."
Type: String
```

Substrings are obtained by giving an index range.

```
hello(1..5)
"Hello"
Type: String
```

```
hello(8..)
"I'm AXIOM!"
Type: String
```

A string can be split into several substrings by giving a separation character or character class.

```
split(hello, char " ")
["Hello", "I'm", "AXIOM!"]
Type: List String
```

```

other := complement alphanumeric();
                                     Type: CharacterClass

split(said saw, other)
["alpha", "omega"]
                                     Type: List String

```

Unwanted characters can be trimmed from the beginning or end of a string using the operations `trim`, `leftTrim` and `rightTrim`.

```

trim("## ++ relax ++ ##", char "#")
" ++ relax ++ "
                                     Type: String

```

Each of these functions takes a string and a second argument to specify the characters to be discarded.

```

trim("## ++ relax ++ ##", other)
"relax"
                                     Type: String

```

The second argument can be given either as a single character or as a character class.

```

leftTrim("## ++ relax ++ ##", other)
"relax ++ ##"
                                     Type: String

rightTrim("## ++ relax ++ ##", other)
"## ++ relax"
                                     Type: String

```

Strings can be changed to upper case or lower case using the operations `upperCase` and `lowerCase`.

```

upperCase hello
"HELLO, I'M AXIOM!"
                                     Type: String

```

The versions with the exclamation mark change the original string, while the others produce a copy.

```

lowerCase hello
"hello, i'm axiom!"
                                     Type: String

```

Some basic string matching is provided. The function `prefix?` tests whether one string is an initial prefix of another.

```

prefix?("He", "Hello")
  true
                                Type: Boolean

```

```

prefix?("Her", "Hello")
  false
                                Type: Boolean

```

A similar function, `suffix?`, tests for suffixes.

```

suffix?("", "Hello")
  true
                                Type: Boolean

```

```

suffix?("LO", "Hello")
  false
                                Type: Boolean

```

The function `substring?` tests for a substring given a starting position.

```

substring?("ll", "Hello", 3)
  true
                                Type: Boolean

```

```

substring?("ll", "Hello", 4)
  false
                                Type: Boolean

```

A number of position functions locate things in strings. If the first argument to `position` is a string, then `position(s,t,i)` finds the location of `s` as a substring of `t` starting the search at position `i`.

```

n := position("nd", "underground", 1)
  2
                                Type: PositiveInteger

```

```

n := position("nd", "underground", n+1)
  10
                                Type: PositiveInteger

```

If `s` is not found, then 0 is returned (`minIndex(s)-1` in `IndexedString`).

```

n := position("nd", "underground", n+1)
  0
                                Type: NonNegativeInteger

```

To search for a specific character or a member of a character class, a different first argument is used.

```

position(char "d", "underground", 1)

```

3

Type: PositiveInteger

position(hexDigit(), "underground", 1)

3

Type: PositiveInteger

=====

StringTable examples

=====

This domain provides a table type in which the keys are known to be strings so special techniques can be used. Other than performance, the type StringTable(S) should behave exactly the same way as Table(String,S).

This creates a new table whose keys are strings.

```

t: StringTable(Integer) := table()
  table()
                                Type: StringTable Integer

```

The value associated with each string key is the number of characters in the string.

```

for s in split("My name is Ian Watt.",char " ")
  repeat
    t.s := #s
                                Type: Void

```

```

for key in keys t repeat output [key, t.key]
["Watt.",5]
["Ian",3]

```

```
["is",2]
["name",4]
["My",2]
```

Type: Void

domain SUBSPACE SubSpace

The first argument *n* is the dimension of the subSpace

The SubSpace domain is implemented as a tree. The root of the tree is the only node in which the field *dataList* - which points to a list of points over the ring, *R* - is defined. The children of the root are the top level components of the SubSpace (in 2D, these would be separate curves; in 3D, these would be separate surfaces).

The *pt* field is only defined in the leaves.

By way of example, consider a three dimensional subspace with two components - a three by three grid and a sphere. The internal representation of this subspace is a tree with a depth of three.

The root holds a list of all the points used in the subspace (so, if the grid and the sphere share points, the shared points would not be represented redundantly but would be referenced by index).

The root, in this case, has two children - the first points to the grid component and the second to the sphere component. The grid child has four children of its own - a 3x3 grid has 4 endpoints - and each of these point to a list of four points. To see it another way, the grid (child of the root) holds a list of line components which, when placed one above the next, forms a grid. Each of these line components is a list of points.

Points could be explicitly added to subspaces at any level. A path could be given as an argument to the `addPoint()` function. It is a list of `NonNegativeIntegers` and refers, in order, to the *n*-th child of the current node. For example,

```
addPoint(s,[2,3],p)
```

would add the point *p* to the subspace *s* by going to the second child of the root and then the third child of that node. If the path does extend to the full depth of the tree, nodes are automatically added so that the tree is of constant depth down any path. By not specifying the full path, new components could be added - e.g. for *s* from `SubSpace(3,Float)`

```
addPoint(s,[],p)
```

would create a new child to the root (a new component in *N*-space) and extend a path to a leaf of depth 3 that points to the data held in *p*. The subspace *s* would now have a new component which has one child which, in turn, has one child (the leaf). The new component is then a point.

++ level component (0 indicates top level component) is being
++ referenced and a component of that level with the desired point
++ is created. The subspace s is returned with the additional point.
modifyPoint   : (%,List NNI,NNI) -> %
++ modifyPoint(s,li,i) replaces an existing point in the 3 dimensional
++ subspace, s, with the 4 dimensional point indicated by the index
++ location, i. The list of non negative integers, li, dictates
++ the path to follow, or, to look at it another way, points to the
++ component in which the existing point is to be modified. An error
++ message occurs if s is empty, otherwise the subspace s is returned
++ with the point modification.
addPoint      : (%,POINT) -> NNI
++ addPoint(s,p) adds the point, p, to the 3 dimensional subspace, s,
++ and returns the new total number of points in s.
modifyPoint   : (%,NNI,POINT) -> %
++ modifyPoint(s,ind,p) modifies the point referenced by the index
++ location, ind, by replacing it with the point, p in the 3 dimensional
++ subspace, s. An error message occurs if s is empty, otherwise the
++ subspace s is returned with the point modification.

closeComponent : (%,List NNI,B)      -> %
++ closeComponent(s,li,b) sets the property of the component in the
++ 3 dimensional subspace, s, to be closed if b is true, or open if
++ b is false. The list of non negative integers, li, dictates the
++ path to follow, or, to look at it another way, points to the
++ component whose closed property is to be set. The subspace, s,
++ is returned with the component property modification.
defineProperty : (%,List NNI,PROP) -> %
++ defineProperty(s,li,p) defines the component property in the
++ 3 dimensional subspace, s, to be that of p, where p is of the
++ domain \spadtype{SubSpaceComponentProperty}. The list of non
++ negative integers, li, dictates the path to follow, or, to look
++ at it another way, points to the component whose property is
++ being defined. The subspace, s, is returned with the component
++ property definition.
traverse      : (%,List NNI) -> %

```

```

    ++ traverse(s,li) follows the branch list of the 3 dimensional
    ++ subspace, s, along the path dictated by the list of non negative
    ++ integers, li, which points to the component which has been
    ++ traversed to. The subspace, s, is returned, where s is now
    ++ the subspace pointed to by li.
extractPoint    : % -> POINT
    ++ extractPoint(s) returns the point which is given by the current
    ++ index location into the point data field of the 3 dimensional
    ++ subspace s.
extractIndex    : % -> NNI
    ++ extractIndex(s) returns a non negative integer which is the current
    ++ index of the 3 dimensional subspace s.
extractClosed   : % -> B
    ++ extractClosed(s) returns the \spadtype{Boolean} value of the closed
    ++ property for the indicated 3 dimensional subspace s. If the
    ++ property is closed, \spad{True} is returned, otherwise \spad{False}
    ++ is returned.
extractProperty : % -> PROP
    ++ extractProperty(s) returns the property of domain
    ++ \spadtype{SubSpaceComponentProperty} of the indicated 3 dimensional
    ++ subspace s.
level          : % -> NNI
    ++ level(s) returns a non negative integer which is the current
    ++ level field of the indicated 3 dimensional subspace s.
parent         : % -> %
    ++ parent(s) returns the subspace which is the parent of the indicated
    ++ 3 dimensional subspace s. If s is the top level subspace an error
    ++ message is returned.
pointData      : % -> L POINT
    ++ pointData(s) returns the list of points from the point data field
    ++ of the 3 dimensional subspace s.

=====

Symbol examples

=====

Symbols are one of the basic types manipulated by Axiom. The Symbol domain provides ways to create symbols of many varieties.

The simplest way to create a symbol is to "single quote" an identifier.

```

X: Symbol := 'x
x

```

Type: Symbol

This gives the symbol even if x has been assigned a value. If x has not been assigned a value, then it is possible to omit the quote.

```

XX: Symbol := x
x

```

Type: Symbol

Declarations must be used when working with symbols, because otherwise the interpreter tries to place values in a more specialized type Variable.

```

A := 'a
a

```

Type: Variable a

```

B := b
b

```

Type: Variable b

The normal way of entering polynomials uses this fact.

```
x**2 + 1
  2
  x  + 1
```

Type: Polynomial Integer

Another convenient way to create symbols is to convert a string. This is useful when the name is to be constructed by a program.

```
"Hello"::Symbol
Hello
```

Type: Symbol

Sometimes it is necessary to generate new unique symbols, for example, to name constants of integration. The expression `new()` generates a symbol starting with %.

```
new()$Symbol
%A
```

Type: Symbol

Successive calls to `new` produce different symbols.

```
new()$Symbol
%B
```

Type: Symbol

The expression `new("s")` produces a symbol starting with %s.

```
new("xyz")$Symbol
%xyz0
```

Type: Symbol

A symbol can be adorned in various ways. The most basic thing is applying a symbol to a list of subscripts.

```
X[i,j]
  x
  i,j
```

Type: Symbol

Somewhat less pretty is to attach subscripts, superscripts or arguments.

```
U := subscript(u, [1,2,1,2])
  u
  1,2,1,2
```

Type: Symbol

```
V := superscript(v, [n])
```

```

n
v
Type: Symbol

```

```
P := argscript(p, [t])
      p(t)
                                         Type: Symbol
```

It is possible to test whether a symbol has scripts using the `scripted?` test.

```
scripted? U
  true
Type: Boolean
```

```
scripted? X
  false
                                         Type: Boolean
```

If a symbol is not scripted, then it may be converted to a string.

```
string X
    "x"
                                     Type: String
```

The basic parts can always be extracted using the name and scripts operations.

```
name U
      u
                                     Type: Symbol
```

```
scripts U
  [sub= [1,2,1,2],sup= [],presup= [],presub= [],args= []]
    Type: Record(sub: List OutputForm,
                  sup: List OutputForm,
                  presup: List OutputForm,
                  presub: List OutputForm,
                  args: List OutputForm)
```

```
name X
  x
                                     Type: Symbol
```

```
scripts X
  [sub= [],sup= [],presup= [],presub= [],args= []]
  Type: Record(sub: List OutputForm,
               sup: List OutputForm,
               presup: List OutputForm,
               presub: List OutputForm,
               args: List OutputForm)
```

The most general form is obtained using the script operation. This operation takes an argument which is a list containing, in this order, lists of subscripts, superscripts, presupscripts, presubscripts and arguments to a symbol.

```
M := script(Mammoth, [ [i,j],[k,l],[0,1],[2],[u,v,w] ])
      0,1      k,l
      Mammoth (u,v,w)
      2      i,j
```

Type: Symbol

```
scripts M
[sub= [i,j],sup= [k,l],presup= [0,1],presub= [2],args= [u,v,w]]
Type: Record(sub: List OutputForm,
             sup: List OutputForm,
             presup: List OutputForm,
             presub: List OutputForm,
             args: List OutputForm)
```

If trailing lists of scripts are omitted, they are assumed to be empty.

```
N := script(Nut, [ [i,j],[k,l],[0,1] ])
      0,1      k,l
      Nut
      i,j
```

Type: Symbol

```
scripts N
[sub= [i,j],sup= [k,l],presup= [0,1],presub= [],args= []]
Type: Record(sub: List OutputForm,
             sup: List OutputForm,
             presup: List OutputForm,
             presub: List OutputForm,
             args: List OutputForm)
```

=====
Table examples
=====

```

The Table constructor provides a general structure for associative storage. This type provides hash tables in which data objects can be saved according to keys of any type. For a given table, specific types must be chosen for the keys and entries.

In this example the keys to the table are polynomials with integer coefficients. The entries in the table are strings.

```

t: Table(Polynomial Integer, String) := table()
table()
                                          Type: Table(Polynomial Integer,String)

```

To save an entry in the table, the setelt operation is used. This can be called directly, giving the table a key and an entry.

```
setelt(t, x**2 - 1, "Easy to factor")
    "Easy to factor"
                                Type: String
```

Alternatively, you can use assignment syntax.

```
t(x**3 + 1) := "Harder to factor"
    "Harder to factor"
                                Type: String
```

```
t(x) := "The easiest to factor"
    "The easiest to factor"
                                Type: String
```

Entries are retrieved from the table by calling the elt operation.

```
elt(t, x)
    "The easiest to factor"
                                Type: String
```

This operation is called when a table is "applied" to a key using this or the following syntax.

```
t.x
    "The easiest to factor"
                                Type: String
```

```
t x
    "The easiest to factor"
                                Type: String
```

Parentheses are used only for grouping. They are needed if the key is an infix expression.

```
t.(x**2 - 1)
    "Easy to factor"
                                Type: String
```

Note that the elt operation is used only when the key is known to be in the table, otherwise an error is generated.

```
t (x**3 + 1)
    "Harder to factor"
                                Type: String
```

You can get a list of all the keys to a table using the keys operation.

```
keys t
      3      2
    [x,x  + 1,x  - 1]
```

Type: List Polynomial Integer

If you wish to test whether a key is in a table, the search operation is used. This operation returns either an entry or "failed".

```
search(x, t)
"The easiest to factor"
Type: Union(String,...)
```

```
search(x**2, t)
"failed"
Type: Union("failed",...)
```

The return type is a union so the success of the search can be tested using case.

```
search(x**2, t) case "failed"
true
Type: Boolean
```

The remove operation is used to delete values from a table.

```
remove!(x**2-1, t)
"Easy to factor"
Type: Union(String,...)
```

If an entry exists under the key, then it is returned. Otherwise remove returns "failed".

```
remove!(x-1, t)
"failed"
Type: Union("failed",...)
```

The number of key-entry pairs can be found using the # operation.

```
#t
2
Type: PositiveInteger
```

Just as keys returns a list of keys to the table, a list of all the entries can be obtained using the members operation.

```
members t
(17) ["The easiest to factor","Harder to factor"]
Type: List String
```

A number of useful operations take functions and map them on to the table to compute the result. Here we count the entries which have "Hard" as a prefix.

```
count(s: String +-> prefix?("Hard", s), t)
1
```

Type: PositiveInteger

Other table types are provided to support various needs.

- o AssociationList gives a list with a table view. This allows new entries to be appended onto the front of the list to cover up old entries. This is useful when table entries need to be stacked or when frequent list traversals are required.
- o EqTable gives tables in which keys are considered equal only when they are in fact the same instance of a structure.
- o StringTable should be used when the keys are known to be strings.
- o SparseTable provides tables with default entries, so lookup never fails. The GeneralSparseTable constructor can be used to make any table type behave this way.
- o KeyedAccessFile allows values to be saved in a file, accessed as a table.

— domain TS TaylorSeries —

```

)abbrev domain TS TaylorSeries
++ Authors: Burge, Watt, Williamson
++ Date Created: 15 August 1988
++ Date Last Updated: 18 May 1991
++ Description:
++ \spadtype{TaylorSeries} is a general multivariate Taylor series domain
++ over the ring Coef and with variables of type Symbol.

TaylorSeries(Coef): Exports == Implementation where
  Coef : Ring
  L ==> List
  NNI ==> NonNegativeInteger
  SMP ==> Polynomial Coef
  StS ==> Stream SMP

Exports ==> MultivariateTaylorSeriesCategory(Coef,Symbol) with
  coefficient: (%,NNI) -> SMP
    ++\spad{coefficient(s, n)} gives the terms of total degree n.
  coerce: Symbol -> %
    ++\spad{coerce(s)} converts a variable to a Taylor series
  coerce: SMP -> %
    ++\spad{coerce(s)} regroups terms of s by total degree
    ++ and forms a series.

if Coef has Algebra Fraction Integer then
  integrate: (%,Symbol,Coef) -> %
    ++\spad{integrate(s,v,c)} is the integral of s with respect
    ++ to v and having c as the constant of integration.
  fintegrate: (() -> %,Symbol,Coef) -> %
    ++\spad{fintegrate(f,v,c)} is the integral of \spad{f()} with respect
    ++ to v and having c as the constant of integration.

```

```

++ The evaluation of \spad{f()} is delayed.

Implementation ==> SparseMultivariateTaylorSeries(Coef,Symbol,SMP) add
Rep := StS -- Below we use the fact that Rep of PS is Stream SMP.

polynomial(s,n) ==
sum : SMP := 0
for i in 0..n while not empty? s repeat
  sum := sum + frst s
  s:= rst s
sum

```

"TS" -> "PSCAT"
"TS" -> "TRANFUN"

```

domain TEX TexFormat

product(product(i*j,i=a..b),j=c..d) fix

The expression prints properly in ascii text but the tex output is incorrect. Originally the input

```
product(product(i*j,i=a..b),j=c..d)
```

prints as

$$(1) \quad PI2(j = c, d, PI2(i = a, b, i j))$$

but now says: The problem is in `[[src/algebra/tex.spad.pamphlet]]` in the list of constants. The code used to read

```

plexOps      : L S := ["SIGMA","SIGMA2","PI","INTSIGN","INDEFINTEGRAL"]$(L S)
plexPrecs    : L I := [ 700, 800,      700,      700]$(L I)

```

it now reads:

— product(product(i*j,i=a..b),j=c..d) fix —

```
plexOps      : L S := ["SIGMA","SIGMA2","PI","PI2","INTSIGN","INDEFINTEGRAL"]$(L S)
plexPrecs    : L I := [ 700, 800, 700, 800 , 700, 700]$(L I)
```

in addition we need to add a line defining `[[PI2]]` in `[[formatPlex]]`:

— **define PI2** —

```
op = "PI2"      => "\prod"
```

— **TexFormat.input** —

```
)set break resume
)sys rm -f TexFormat.output
)spool TexFormat.output
)set message test on
)set message auto off
)clear all
```

=====

TexFormat examples

=====

You can ask Axiom to show latex output. In particular, this can be used for complex output.

(1/2)::TEX

["\$\$", "\frac{1}{2} ", "\$\$"]

```
(1/(x+5))::TEX
```

```
["$${\frac{1}{{x+5}}} ", "$$"]
```

```
((x+3)/(y-5))::TEX
```

```
["$${\frac{{x+3}}{{y-5}}} ", "$$"]
```

We can change the fraction display so it is horizontal:

```
)set output fraction horizontal
```

```
(1/2)::TEX
```

```
["$${\left(1, \right)} ", "$$"]
```

```
(1/(x+5))::TEX
```

```
["$${\left(1, \right)} ", "$$"]
```

```
((x+3)/(y-5))::TEX
```

```
["$${\left({x+3}, \right)} ", "$$"]
```

— domain TEX TexFormat —

```
)abbrev domain TEX TexFormat
++ Author: Robert S. Sutor
++ Date Created: 1987 through 1992
++ Description:
++ \spadtype{TexFormat} provides a coercion from \spadtype{OutputForm} to
++ \TeX{} format. The particular dialect of \TeX{} used is \LaTeX{}.
++ The basic object consists of three parts: a prologue, a
++ tex part and an epilogue. The functions \spadfun{prologue},
++ \spadfun{tex} and \spadfun{epilogue} extract these parts,
++ respectively. The main guts of the expression go into the tex part.
++ The other parts can be set (\spadfun{setPrologue!},
++ \spadfun{setEpilogue!}) so that contain the appropriate tags for
++ printing. For example, the prologue and epilogue might simply
++ contain ‘\verb+[+’ and ‘\verb+]+’, respectively, so that
++ the TeX section will be printed in LaTeX display math mode.
```

```
TexFormat(): public == private where
E      ==> OutputForm
I      ==> Integer
L      ==> List
S      ==> String
US     ==> UniversalSegment(Integer)
```

```
public == SetCategory with
coerce: E -> $
++ coerce(o) changes o in the standard output format to TeX
++ format.
convert: (E,I) -> $
++ convert(o,step) changes o in standard output format to
++ TeX format and also adds the given step number. This is useful
++ if you want to create equations with given numbers or have the
++ equation numbers correspond to the interpreter step numbers.
convert: (E,I,E) -> $
++ convert(o,step,type) changes o in standard output format to
++ TeX format and also adds the given step number and type. This
++ is useful if you want to create equations with given numbers
++ or have the equation numbers correspond to the interpreter step
++ numbers.
display: ($, I) -> Void
++ display(t,width) outputs the TeX formatted code t so that each
++ line has length less than or equal to \spadvar{width}.
display: $ -> Void
++ display(t) outputs the TeX formatted code t so that each
```

```

++ line has length less than or equal to the value set by
++ the system command \spadsyscom{set output length}.
epilogue: $ -> L S
++ epilogue(t) extracts the epilogue section of a TeX form t.
tex:      $ -> L S
++ tex(t) extracts the TeX section of a TeX form t.
new:      () -> $
++ new() create a new, empty object. Use \spadfun{setPrologue!},
++ \spadfun{setTex!} and \spadfun{setEpilogue!} to set the various
++ components of this object.
prologue: $ -> L S
++ prologue(t) extracts the prologue section of a TeX form t.
setEpilogue!: ($, L S) -> L S
++ setEpilogue!(t,strings) sets the epilogue section of a TeX form t
++ to strings.
setTex!: ($, L S) -> L S
++ setTex!(t,strings) sets the TeX section of a TeX form t to strings.
setPrologue!: ($, L S) -> L S
++ setPrologue!(t,strings) sets the prologue section of a TeX form t
++ to strings.

=====

TextFile examples

=====

The domain TextFile allows Axiom to read and write character data and exchange text with other programs. This type behaves in Axiom much like a File of strings, with additional operations to cause new lines. We give an example of how to produce an upper case copy of a file.

This is the file from which we read the text.

```
f1: TextFile := open("/etc/group", "input")
"/etc/group"
Type: TextFile
```

This is the file to which we write the text.

```
f2: TextFile := open("/tmp/MOTD", "output")
"MOTD"
Type: TextFile
```

Entire lines are handled using the readLine and writeLine operations.

```
l := readLine! f1
"root:x:0:root"
Type: String

writeLine!(f2, upperCase l)
"ROOT:X:0:ROOT"
Type: String
```

Use the endOfFile? operation to check if you have reached the end of the file.

```
while not endOfFile? f1 repeat
  s := readLine! f1
  writeLine!(f2, upperCase s)
Type: Void
```

The file f1 is exhausted and should be closed.

```
close! f1
"/etc/group"
Type: TextFile
```

It is sometimes useful to write lines a bit at a time. The write operation allows this.

```
write!(f2, "-The-")
"-The-"
Type: String

write!(f2, "-End-")
"-End-"
Type: String
```

This ends the line. This is done in a machine-dependent manner.

```
writeLine! f2
""
```

Type: String

```
close! f2
"MTD"
```

Type: TextFile

Finally, clean up.

```
)system rm /tmp/MTD
```

— domain TEXTFILE TextFile —

```

)abbrev domain TEXTFILE TextFile
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides an implementation of text files. Text is stored
++ in these files using the native character set of the computer.

TextFile: Cat == Def where
  StreamName ==> Union(FileName, "console")

  Cat == FileCategory(FileName, String) with
    writeLine_!: (%, String) -> String
      ++ writeLine!(f,s) writes the contents of the string s
      ++ and finishes the current line in the file f.
      ++ The value of s is returned.

    writeLine_!: % -> String
      ++ writeLine!(f) finishes the current line in the file f.
      ++ An empty string is returned. The call \spad{writeLine!(f)} is
      ++ equivalent to \spad{writeLine!(f,"")}.

    readLine_!: % -> String
      ++ readLine!(f) returns a string of the contents of a line from
      ++ the file f.

    readLineIfCan_!: % -> Union(String, "failed")
      ++ readLineIfCan!(f) returns a string of the contents of a line from
      ++ file f, if possible. If f is not readable or if it is
      ++ positioned at the end of file, then \spad{"failed"} is returned.

    readIfCan_!: % -> Union(String, "failed")
      ++ readIfCan!(f) returns a string of the contents of a line from
      ++ file f, if possible. If f is not readable or if it is
      ++ positioned at the end of file, then \spad{"failed"} is returned.

    endOfFile?: % -> Boolean
      ++ endOfFile?(f) tests whether the file f is positioned after the
      ++ end of all text. If the file is open for output, then
      ++ this test is always true.

  Def == File(String) add

Exports ==> SetCategory with
  viewThetaDefault      : ()                                -> F
  ++ viewThetaDefault() returns the current default longitudinal
  ++ view angle in radians.
  viewThetaDefault      : F                                -> F
  ++ viewThetaDefault(t) sets the current default longitudinal
  ++ view angle in radians to the value t and returns t.
  viewPhiDefault        : ()                                -> F
  ++ viewPhiDefault() returns the current default latitudinal
  ++ view angle in radians.
  viewPhiDefault        : F                                -> F

```

```

    ++ viewPhiDefault(p) sets the current default latitudinal
    ++ view angle in radians to the value p and returns p.
viewZoomDefault      : ()                                -> F
    ++ viewZoomDefault() returns the current default graph scaling
    ++ value.
viewZoomDefault      : F                                -> F
    ++ viewZoomDefault(s) sets the current default graph scaling
    ++ value to s and returns s.
viewDeltaXDefault    : ()                                -> F
    ++ viewDeltaXDefault() returns the current default horizontal
    ++ offset from the center of the viewport window.
viewDeltaXDefault    : F                                -> F
    ++ viewDeltaXDefault(dx) sets the current default horizontal
    ++ offset from the center of the viewport window to be \spad{dx}
    ++ and returns \spad{dx}.
viewDeltaYDefault    : ()                                -> F
    ++ viewDeltaYDefault() returns the current default vertical
    ++ offset from the center of the viewport window.
viewDeltaYDefault    : F                                -> F
    ++ viewDeltaYDefault(dy) sets the current default vertical
    ++ offset from the center of the viewport window to be \spad{dy}
    ++ and returns \spad{dy}.
viewport3D           : ()                                -> %
    ++ viewport3D() returns an undefined three-dimensional viewport
    ++ of the domain \spadtype{ThreeDimensionalViewport} whose
    ++ contents are empty.
makeViewport3D       : %                                -> %
    ++ makeViewport3D(v) takes the given three-dimensional viewport,
    ++ v, of the domain \spadtype{ThreeDimensionalViewport} and
    ++ displays a viewport window on the screen which contains
    ++ the contents of v.
makeViewport3D       : (SPACE3,S)                       -> %
    ++ makeViewport3D(sp,s) takes the given space, \spad{sp} which is
    ++ of the domain \spadtype{ThreeSpace} and displays a viewport
    ++ window on the screen which contains the contents of \spad{sp},
    ++ and whose title is given by s.
makeViewport3D       : (SPACE3,L DROP)                   -> %
    ++ makeViewport3D(sp,lopt) takes the given space, \spad{sp} which is
    ++ of the domain \spadtype{ThreeSpace} and displays a viewport
    ++ window on the screen which contains the contents of \spad{sp},
    ++ and whose draw options are indicated by the list \spad{lopt}, which
    ++ is a list of options from the domain \spad{DrawOption}.
subspace             : %                                -> SPACE3
    ++ subspace(v) returns the contents of the viewport v, which is
    ++ of the domain \spadtype{ThreeDimensionalViewport}, as a subspace
    ++ of the domain \spad{ThreeSpace}.
subspace             : (% ,SPACE3)                       -> %
    ++ subspace(v,sp) places the contents of the viewport v, which is
    ++ of the domain \spadtype{ThreeDimensionalViewport}, in the subspace
    ++ \spad{sp}, which is of the domain \spad{ThreeSpace}.

```

```

modifyPointData      : (%,NNI,POINT)                                -> Void
++ modifyPointData(v,ind,pt) takes the viewport, v, which is of the
++ domain \spadtype{ThreeDimensionalViewport}, and places the data
++ point, \spad{pt} into the list of points database of v at the index
++ location given by \spad{ind}.
options              : %                                           -> L DROP
++ options(v) takes the viewport, v, which is of the domain
++ \spadtype{ThreeDimensionalViewport} and returns a list of all
++ the draw options from the domain \spad{DrawOption} which are
++ being used by v.
options              : (%,L DROP)                                   -> %
++ options(v,lopt) takes the viewport, v, which is of the domain
++ \spadtype{ThreeDimensionalViewport} and sets the draw options
++ being used by v to those indicated in the list, \spad{lopt},
++ which is a list of options from the domain \spad{DrawOption}.
move                 : (%,NNI,NNI)                                  -> Void
++ move(v,x,y) displays the three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, with the upper
++ left-hand corner of the viewport window at the screen
++ coordinate position x, y.
resize               : (%,PI,PI)                                    -> Void
++ resize(v,w,h) displays the three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, with a width
++ of w and a height of h, keeping the upper left-hand corner
++ position unchanged.
title                : (%,S)                                        -> Void
++ title(v,s) changes the title which is shown in the three-dimensional
++ viewport window, v of domain \spadtype{ThreeDimensionalViewport}.
dimensions           : (%,NNI,NNI,PI,PI)                           -> Void
++ dimensions(v,x,y,width,height) sets the position of the
++ upper left-hand corner of the three-dimensional viewport, v,
++ which is of domain \spadtype{ThreeDimensionalViewport}, to
++ the window coordinate x, y, and sets the dimensions of the
++ window to that of \spad{width}, \spad{height}. The new
++ dimensions are not displayed until the function
++ \spadfun{makeViewport3D} is executed again for v.
viewpoint            : (%,F,F,F,F,F)                               -> Void
++ viewpoint(v,th,phi,s,dx,dy) sets the longitudinal view angle
++ to \spad{th} radians, the latitudinal view angle to \spad{phi}
++ radians, the scale factor to \spad{s}, the horizontal viewport
++ offset to \spad{dx}, and the vertical viewport offset to \spad{dy}
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new viewpoint position
++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.
viewpoint            : (%) -> V
++ viewpoint(v) returns the current viewpoint setting of the given
++ viewport, v. This function is useful in the situation where the
++ user has created a viewport, proceeded to interact with it via
++ the control panel and desires to save the values of the viewpoint

```

```

++ as the default settings for another viewport to be created using
++ the system.
viewpoint : (%,V) -> Void
++ viewpoint(v,viewpt) sets the viewpoint for the viewport. The
++ viewport record consists of the latitudinal and longitudinal angles,
++ the zoom factor, the x,y and z scales, and the x and y displacements.
viewpoint      : (%,I,I,F,F,F) -> Void
++ viewpoint(v,th,phi,s,dx,dy) sets the longitudinal view angle
++ to \spad{th} degrees, the latitudinal view angle to \spad{phi}
++ degrees, the scale factor to \spad{s}, the horizontal viewport
++ offset to \spad{dx}, and the vertical viewport offset to \spad{dy}
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new viewpoint position
++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.
viewpoint      : (%,F,F,F) -> Void
++ viewpoint(v,th,phi) sets the longitudinal view angle to \spad{th}
++ radians and the latitudinal view angle to \spad{phi} radians
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new viewpoint position
++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.
viewpoint      : (%,F,F,F,F) -> Void
++ viewpoint(v,rotx,roty,rotz) sets the rotation about the x-axis
++ to be \spad{rotx} radians, sets the rotation about the y-axis
++ to be \spad{roty} radians, and sets the rotation about the z-axis
++ to be \spad{rotz} radians, for the viewport v, which is of the
++ domain \spadtype{ThreeDimensionalViewport} and displays v with
++ the new view position.
controlPanel   : (%,S) -> Void
++ controlPanel(v,s) displays the control panel of the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or hides
++ the control panel if s is "off".
axes           : (%,S) -> Void
++ axes(v,s) displays the axes of the given three-dimensional
++ viewport, v, which is of domain \spadtype{ThreeDimensionalViewport},
++ if s is "on", or does not display the axes if s is "off".
diagonals      : (%,S) -> Void
++ diagonals(v,s) displays the diagonals of the polygon outline
++ showing a triangularized surface instead of a quadrilateral
++ surface outline, for the given three-dimensional viewport v
++ which is of domain \spadtype{ThreeDimensionalViewport}, if s is
++ "on", or does not display the diagonals if s is "off".
outlineRender  : (%,S) -> Void
++ outlineRender(v,s) displays the polygon outline showing either
++ triangularized surface or a quadrilateral surface outline depending
++ on the whether the \spadfun{diagonals} function has been set, for
++ the given three-dimensional viewport v which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not

```

```

++ display the polygon outline if s is "off".
drawStyle      : (%,S)                                -> Void
++ drawStyle(v,s) displays the surface for the given three-dimensional
++ viewport v which is of domain \spadtype{ThreeDimensionalViewport}
++ in the style of drawing indicated by s. If s is not a valid
++ drawing style the style is wireframe by default. Possible
++ styles are \spad{"shade"}, \spad{"solid"} or \spad{"opaque"},
++ \spad{"smooth"}, and \spad{"wireMesh"}.
rotate        : (%,F,F)                                -> Void
++ rotate(v,th,phi) rotates the graph to the longitudinal view angle
++ \spad{th} radians and the latitudinal view angle \spad{phi} radians
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}.
rotate        : (%,I,I)                                -> Void
++ rotate(v,th,phi) rotates the graph to the longitudinal view angle
++ \spad{th} degrees and the latitudinal view angle \spad{phi} degrees
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new rotation position
++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.
zoom          : (%,F)                                    -> Void
++ zoom(v,s) sets the graph scaling factor to s, for the viewport v,
++ which is of the domain \spadtype{ThreeDimensionalViewport}.
zoom          : (%,F,F,F)                                -> Void
++ zoom(v,sx,sy,sz) sets the graph scaling factors for the x-coordinate
++ axis to \spad{sx}, the y-coordinate axis to \spad{sy} and the
++ z-coordinate axis to \spad{sz} for the viewport v, which is of
++ the domain \spadtype{ThreeDimensionalViewport}.
translate     : (%,F,F)                                    -> Void
++ translate(v,dx,dy) sets the horizontal viewport offset to \spad{dx}
++ and the vertical viewport offset to \spad{dy}, for the viewport v,
++ which is of the domain \spadtype{ThreeDimensionalViewport}.
perspective   : (%,S)                                    -> Void
++ perspective(v,s) displays the graph in perspective if s is "on",
++ or does not display perspective if s is "off" for the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.
eyeDistance   : (%,F)                                    -> Void
++ eyeDistance(v,d) sets the distance of the observer from the center
++ of the graph to d, for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}.
hitherPlane   : (%,F)                                    -> Void
++ hitherPlane(v,h) sets the hither clipping plane of the graph to h,
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}.
showRegion    : (%,S)                                    -> Void
++ showRegion(v,s) displays the bounding box of the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not
++ display the box if s is "off".

```

```

showClipRegion      : (%,S)                                -> Void
++ showClipRegion(v,s) displays the clipping region of the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not
++ display the region if s is "off".
clipSurface         : (%,S)                                -> Void
++ clipSurface(v,s) displays the graph with the specified
++ clipping region removed if s is "on", or displays the graph
++ without clipping implemented if s is "off", for the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.
lighting            : (%,F,F,F)                            -> Void
++ lighting(v,x,y,z) sets the position of the light source to
++ the coordinates x, y, and z and displays the graph for the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.
intensity           : (%,F)                                -> Void
++ intensity(v,i) sets the intensity of the light source to i, for
++ the given three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.
reset               : %                                     -> Void
++ reset(v) sets the current state of the graph characteristics
++ of the given three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, back to their initial settings.
colorDef            : (%,C,C)                              -> Void
++ colorDef(v,c1,c2) sets the range of colors along the colormap so
++ that the lower end of the colormap is defined by \spad{c1} and the
++ top end of the colormap is defined by \spad{c2}, for the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.
write               : (%,S)                                -> S
++ write(v,s) takes the given three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ file for v.
write               : (%,S,S)                              -> S
++ write(v,s,f) takes the given three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ file for v and an optional file type f.
write               : (%,S,L S)                            -> S
++ write(v,s,lf) takes the given three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ file for v and the optional file types indicated by the list lf.
close               : %                                     -> Void
++ close(v) closes the viewport window of the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, and terminates the
++ corresponding process ID.

```

```

key          : %                                -> I
++ key(v) returns the process ID number of the given three-dimensional
++ viewport, v, which is of domain \spadtype{ThreeDimensionalViewport}.
-- print      : %                                -> Void

— domain TREE Tree —

```
)abbrev domain TREE Tree
++ Author:W. H. Burge
++ Date Created:17 Feb 1992
++ Description:
++ \spadtype{Tree(S)} is a basic domains of tree structures.
++ Each tree is either empty or else is a node consisting of a value and
++ a list of (sub)trees.
```

```
Tree(S: SetCategory): T==C where
  T== RecursiveAggregate(S) with
    finiteAggregate
    shallowlyMutable
  tree: (S,List %) -> %
    ++ tree(nd,ls) creates a tree with value nd, and children ls.
    ++
    ++X t1:=tree [1,2,3,4]
    ++X tree(5,[t1])

  tree: List S -> %
    ++ tree(ls) creates a tree from a list of elements of s.
    ++
    ++X tree [1,2,3,4]

  tree: S -> %
    ++ tree(nd) creates a tree with value nd, and no children
    ++
    ++X tree 6

  cyclic?: % -> Boolean
    ++ cyclic?(t) tests if t is a cyclic tree.
    ++
```

```

++X t1:=tree [1,2,3,4]
++X cyclic? t1

cyclicCopy: % -> %
++ cyclicCopy(l) makes a copy of a (possibly) cyclic tree l.
++
++X t1:=tree [1,2,3,4]
++X cyclicCopy t1

cyclicEntries: % -> List %
++ cyclicEntries(t) returns a list of top-level cycles in tree t.
++
++X t1:=tree [1,2,3,4]
++X cyclicEntries t1

cyclicEqual?: (% , %) -> Boolean
++ cyclicEqual?(t1, t2) tests if two cyclic trees have
++ the same structure.
++
++X t1:=tree [1,2,3,4]
++X t2:=tree [1,2,3,4]
++X cyclicEqual?(t1,t2)

cyclicParents: % -> List %
++ cyclicParents(t) returns a list of cycles that are parents of t.
++
++X t1:=tree [1,2,3,4]
++X cyclicParents t1

=====
TwoDimensionalArray examples
=====

```

The TwoDimensionalArray domain is used for storing data in a two dimensional data structure indexed by row and by column. Such an array is a homogeneous data structure in that all the entries of the array must belong to the same Axiom domain.. Each array has a fixed number of rows and columns specified by the user and arrays are not extensible. In Axiom, the indexing of two-dimensional arrays is one-based. This means that both the "first" row of an array and the "first" column of an array are given the index 1. Thus, the entry in the upper left corner of an array is in position (1,1).

The operation new creates an array with a specified number of rows and

columns and fills the components of that array with a specified entry. The arguments of this operation specify the number of rows, the number of columns, and the entry.

This creates a five-by-four array of integers, all of whose entries are zero.

```
arr : ARRAY2 INT := new(5,4,0)
+0  0  0  0+
|
|0  0  0  0|
|
|0  0  0  0|
|
|0  0  0  0|
|
+0  0  0  0+
```

Type: TwoDimensionalArray Integer

The entries of this array can be set to other integers using `setelt`.

Issue this to set the element in the upper left corner of this array to 17.

```
setelt(arr,1,1,17)
17
```

Type: PositiveInteger

Now the first element of the array is 17.

```
arr
+17  0  0  0+
|
|0  0  0  0|
|
|0  0  0  0|
|
|0  0  0  0|
|
+0  0  0  0+
```

Type: TwoDimensionalArray Integer

Likewise, elements of an array are extracted using the operation `elt`.

```
elt(arr,1,1)
17
```

Type: PositiveInteger

Another way to use these two operations is as follows. This sets the element in position (3,2) of the array to 15.

```
arr(3,2) := 15
15
```

Type: PositiveInteger

This extracts the element in position (3,2) of the array.

```
arr(3,2)
15
```

Type: PositiveInteger

The operations `elt` and `setelt` come equipped with an error check which verifies that the indices are in the proper ranges. For example, the above array has five rows and four columns, so if you ask for the entry in position (6,2) with `arr(6,2)` Axiom displays an error message. If there is no need for an error check, you can call the operations `qelt` and `qsetelt` which provide the same functionality but without the error check. Typically, these operations are called in well-tested programs.

The operations `row` and `column` extract rows and columns, respectively, and return objects of `OneDimensionalArray` with the same underlying element type.

```
row(arr,1)
[17,0,0,0]
```

Type: OneDimensionalArray Integer

```
column(arr,1)
[17,0,0,0,0]
```

Type: OneDimensionalArray Integer

You can determine the dimensions of an array by calling the operations `nrows` and `ncols`, which return the number of rows and columns, respectively.

```
nrows(arr)
5
```

Type: PositiveInteger

```
ncols(arr)
4
```

Type: PositiveInteger

To apply an operation to every element of an array, use `map`. This creates a new array. This expression negates every element.

```
map(-,arr)
+- 17  0  0  0+
|      |
| 0    0  0  0|
|      |
| 0  - 15 0  0|
```

```

|
| 0    0    0 0|
|
+ 0    0    0 0+
Type: TwoDimensionalArray Integer

```

This creates an array where all the elements are doubled.

```

map((x +-> x + x),arr)
+34 0    0    0+
|
| 0    0    0 0|
|
| 0    30   0 0|
|
| 0    0    0 0|
|
+0   0    0    0+
Type: TwoDimensionalArray Integer

```

To change the array destructively, use `map` instead of `map`. If you need to make a copy of any array, use `copy`.

```

arrc := copy(arr)
+17 0    0    0+
|
| 0    0    0 0|
|
| 0    15   0 0|
|
| 0    0    0 0|
|
+0   0    0    0+
Type: TwoDimensionalArray Integer

```

```

map!(-,arrc)
+- 17 0    0    0+
|
| 0    0    0 0|
|
| 0    - 15  0 0|
|
| 0    0    0 0|
|
+ 0    0    0 0+
Type: TwoDimensionalArray Integer

```

```

arrc
+- 17 0    0    0+
|
|

```

```

| 0      0      0  0|
|          |
| 0      - 15    0  0|
|          |
| 0      0      0  0|
|          |
+ 0      0      0  0+
Type: TwoDimensionalArray Integer

```

```

arr
+17  0      0  0+
|          |
| 0      0      0  0|
|          |
| 0      15    0  0|
|          |
| 0      0      0  0|
|          |
+0    0      0  0+
Type: TwoDimensionalArray Integer

```

Use `member?` to see if a given element is in an array.

```

member?(17,arr)
true
Type: Boolean

```

```

member?(10317,arr)
false
Type: Boolean

```

To see how many times an element appears in an array, use `count`.

```

count(17,arr)
1
Type: PositiveInteger

```

```

count(0,arr)
18
Type: PositiveInteger

```

  getPickedPoints : $ -> L POINT
  ++ getPickedPoints(x)
  ++ returns a list of small floats for the points the
  ++ user interactively picked on the viewport
  ++ for full integration into the system, some design
  ++ issues need to be addressed: e.g. how to go through
  ++ the GraphImage interface, how to default to graphs, etc.
viewport2D : () -> $

```

```

++ viewport2D() returns an undefined two-dimensional viewport
++ of the domain \spadtype{TwoDimensionalViewport} whose
++ contents are empty.
makeViewport2D : $                                -> $
++ makeViewport2D(v) takes the given two-dimensional viewport,
++ v, of the domain \spadtype{TwoDimensionalViewport} and
++ displays a viewport window on the screen which contains
++ the contents of v.
options      : $                                -> L DROP
++ options(v) takes the given two-dimensional viewport, v, of the
++ domain \spadtype{TwoDimensionalViewport} and returns a list
++ containing the draw options from the domain \spadtype{DrawOption}
++ for v.
options      : ($,L DROP)                        -> $
++ options(v,lopt) takes the given two-dimensional viewport, v,
++ of the domain \spadtype{TwoDimensionalViewport} and returns
++ v with it's draw options modified to be those which are indicated
++ in the given list, \spad{lopt} of domain \spadtype{DrawOption}.
makeViewport2D : (G,L DROP)                       -> $
++ makeViewport2D(gi,lopt) creates and displays a viewport window
++ of the domain \spadtype{TwoDimensionalViewport} whose graph
++ field is assigned to be the given graph, \spad{gi}, of domain
++ \spadtype{GraphImage}, and whose options field is set to be
++ the list of options, \spad{lopt} of domain \spadtype{DrawOption}.
graphState   : ($,PI,SF,SF,SF,SF,I,I,I,I,PAL,I,PAL,I) -> Void
++ graphState(v,num,sX,sY,dX,dY,pts,lns,box,axes,axesC,un,unC,cP)
++ sets the state of the characteristics for the graph indicated
++ by \spad{num} in the given two-dimensional viewport v, of domain
++ \spadtype{TwoDimensionalViewport}, to the values given as
++ parameters. The scaling of the graph in the x and y component
++ directions is set to be \spad{sX} and \spad{sY}; the window
++ translation in the x and y component directions is set to be
++ \spad{dX} and \spad{dY}; The graph points, lines, bounding box,
++ axes, or units will be shown in the viewport if their given
++ parameters \spad{pts}, \spad{lns}, \spad{box}, \spad{axes} or
++ \spad{un} are set to be \spad{1}, but will not be shown if they
++ are set to \spad{0}. The color of the axes and the color of the
++ units are indicated by the palette colors \spad{axesC} and
++ \spad{unC} respectively. To display the control panel when
++ the viewport window is displayed, set \spad{cP} to \spad{1},
++ otherwise set it to \spad{0}.
graphStates  : $                                -> V GS
++ graphStates(v) returns and shows a listing of a record containing
++ the current state of the characteristics of each of the ten graph
++ records in the given two-dimensional viewport, v, which is of
++ domain \spadtype{TwoDimensionalViewport}.
graphs      : $                                -> V GU
++ graphs(v) returns a vector, or list, which is a union of all
++ the graphs, of the domain \spadtype{GraphImage}, which are
++ allocated for the two-dimensional viewport, v, of domain

```

```

++ \spadtype{TwoDimensionalViewport}. Those graphs which have
++ no data are labeled "undefined", otherwise their contents
++ are shown.
title      : ($,STR)                                -> Void
++ title(v,s) changes the title which is shown in the two-dimensional
++ viewport window, v of domain \spadtype{TwoDimensionalViewport}.
putGraph   : ($,G,PI)                                -> Void
++ putGraph(v,gi,n) sets the graph field indicated by n, of the
++ indicated two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, to be the graph, \spad{gi}
++ of domain \spadtype{GraphImage}. The contents of viewport, v,
++ will contain \spad{gi} when the function \spadfun{makeViewport2D}
++ is called to create the an updated viewport v.
getGraph   : ($,PI)                                  -> G
++ getGraph(v,n) returns the graph which is of the domain
++ \spadtype{GraphImage} which is located in graph field n
++ of the given two-dimensional viewport, v, which is of the
++ domain \spadtype{TwoDimensionalViewport}.
axes       : ($,PI,STR)                              -> Void
++ axes(v,n,s) displays the axes of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
++ not display the axes if s is "off".
axes       : ($,PI,PAL)                              -> Void
++ axes(v,n,c) displays the axes of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, with the axes color set to
++ the given palette color c.
units      : ($,PI,STR)                              -> Void
++ units(v,n,s) displays the units of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
++ not display the units if s is "off".
units      : ($,PI,PAL)                              -> Void
++ units(v,n,c) displays the units of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, with the units color set to
++ the given palette color c.
points     : ($,PI,STR)                              -> Void
++ points(v,n,s) displays the points of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
++ not display the points if s is "off".
region     : ($,PI,STR)                              -> Void
++ region(v,n,s) displays the bounding box of the graph in
++ field n of the given two-dimensional viewport, v, which is
++ of domain \spadtype{TwoDimensionalViewport}, if s is "on",
++ or does not display the bounding box if s is "off".
connect    : ($,PI,STR)                              -> Void
++ connect(v,n,s) displays the lines connecting the graph

```

```

++ points in field n of the given two-dimensional viewport, v,
++ which is of domain \spadtype{TwoDimensionalViewport}, if s
++ is "on", or does not display the lines if s is "off".
controlPanel    : ($,STR)                                -> Void
++ controlPanel(v,s) displays the control panel of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or hides
++ the control panel if s is "off".
close           : $                                       -> Void
++ close(v) closes the viewport window of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, and terminates the
++ corresponding process ID.
dimensions      : ($,NNI,NNI,PI,PI)                      -> Void
++ dimensions(v,x,y,width,height) sets the position of the
++ upper left-hand corner of the two-dimensional viewport, v,
++ which is of domain \spadtype{TwoDimensionalViewport}, to
++ the window coordinate x, y, and sets the dimensions of the
++ window to that of \spad{width}, \spad{height}. The new
++ dimensions are not displayed until the function
++ \spadfun{makeViewport2D} is executed again for v.
scale           : ($,PI,F,F)                             -> Void
++ scale(v,n,sx,sy) displays the graph in field n of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, scaled by the factor \spad{sx}
++ in the x-coordinate direction and by the factor \spad{sy} in
++ the y-coordinate direction.
translate       : ($,PI,F,F)                             -> Void
++ translate(v,n,dx,dy) displays the graph in field n of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, translated by \spad{dx} in
++ the x-coordinate direction from the center of the viewport, and
++ by \spad{dy} in the y-coordinate direction from the center.
++ Setting \spad{dx} and \spad{dy} to \spad{0} places the center
++ of the graph at the center of the viewport.
show           : ($,PI,STR)                              -> Void
++ show(v,n,s) displays the graph in field n of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or does not
++ display the graph if s is "off".
move           : ($,NNI,NNI)                             -> Void
++ move(v,x,y) displays the two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport}, with the upper
++ left-hand corner of the viewport window at the screen
++ coordinate position x, y.
update         : ($,G,PI)                                -> Void
++ update(v,gr,n) drops the graph \spad{gr} in slot \spad{n}
++ of viewport \spad{v}. The graph gr must have been
++ transmitted already and acquired an integer key.
resize        : ($,PI,PI)                                -> Void

```

```

++ resize(v,w,h) displays the two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport}, with a width
++ of w and a height of h, keeping the upper left-hand corner
++ position unchanged.
write      : ($,STR)                                -> STR
++ write(v,s) takes the given two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ files for v.
write      : ($,STR,STR)                            -> STR
++ write(v,s,f) takes the given two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ files for v and an optional file type f.
write      : ($,STR,L STR)                          -> STR
++ write(v,s,lf) takes the given two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ files for v and the optional file types indicated by the list lf.
reset      : $                                       -> Void
++ reset(v) sets the current state of the graph characteristics
++ of the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, back to their initial settings.
key        : $                                       -> I
++ key(v) returns the process ID number of the given two-dimensional
++ viewport, v, which is of domain \spadtype{TwoDimensionalViewport}.
coerce     : $                                       -> E
++ coerce(v) returns the given two-dimensional viewport, v, which
++ is of domain \spadtype{TwoDimensionalViewport} as output of
++ the domain \spadtype{OutputForm}.

=====
UnivariateLaurentSeries examples
=====

```

UnivariateLaurentSeries is a domain representing Laurent series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, `UnivariateLaurentSeries(Integer,x,3)` represents Laurent series in $(x - 3)$ with integer coefficients.

)abbrev domain ULS UnivariateLaurentSeries
++ Author: Clifton J. Williamson
++ Date Created: 18 January 1990
++ Date Last Updated: 21 September 1993
++ Description:
++ Dense Laurent series in one variable
++ \spadtype{UnivariateLaurentSeries} is a domain representing Laurent
++ series in one variable with coefficients in an arbitrary ring. The
++ parameters of the type specify the coefficient ring, the power series
++ variable, and the center of the power series expansion. For example,
++ \spad{UnivariateLaurentSeries(Integer,x,3)} represents Laurent series in
++ \spad{(x - 3)} with integer coefficients.

UnivariateLaurentSeries(Coef,var,cen): Exports == Implementation where
  Coef : Ring
  var  : Symbol
  cen  : Coef
  I    ==> Integer
  UTS  ==> UnivariateTaylorSeries(Coef,var,cen)

Exports ==> UnivariateLaurentSeriesConstructorCategory(Coef,UTS) with
  coerce: Variable(var) -> %
    ++ \spad{coerce(var)} converts the series variable \spad{var} into a
    ++ Laurent series.
  differentiate: (% ,Variable(var)) -> %
    ++ \spad{differentiate(f(x),x)} returns the derivative of
    ++ \spad{f(x)} with respect to \spad{x}.
  if Coef has Algebra Fraction Integer then
    integrate: (% ,Variable(var)) -> %
      ++ \spad{integrate(f(x))} returns an anti-derivative of the power
      ++ series \spad{f(x)} with constant coefficient 0.
      ++ We may integrate a series when we can divide coefficients
      ++ by integers.

Implementation ==> UnivariateLaurentSeriesConstructor(Coef,UTS) add

  variable x == var
  center   x == cen

  coerce(v:Variable(var)) ==
    zero? cen => monomial(1,1)
    monomial(1,1) + monomial(cen,0)

  differentiate(x:% ,v:Variable(var)) == differentiate x

  if Coef has Algebra Fraction Integer then
    integrate(x:% ,v:Variable(var)) == integrate x

=====
UnivariateLaurentSeriesConstructor examples
=====

```

This package enables one to construct a univariate Laurent series domain from a univariate Taylor series domain. Univariate Laurent series are represented by a pair $[n, f(x)]$, where n is an arbitrary integer and $f(x)$ is a Taylor series. This pair represents the Laurent series $x^n * f(x)$.

=====

UnivariatePolynomial examples

=====

The domain constructor `UnivariatePolynomial` (abbreviated `UP`) creates domains of univariate polynomials in a specified variable. For example, the domain `UP(a1,POLY FRAC INT)` provides polynomials in the single variable `a1` whose coefficients are general polynomials with rational number coefficients.

Restriction: Axiom does not allow you to create types where `UnivariatePolynomial` is contained in the coefficient type of `Polynomial`. Therefore, `UP(x,POLY INT)` is legal but `POLY UP(x,INT)` is not.

`UP(x,INT)` is the domain of polynomials in the single variable `x` with integer coefficients.

```
(p,q) : UP(x,INT)
                                Type: Void

p := (3*x-1)**2 * (2*x + 8)
      3      2
    18x  + 60x  - 46x + 8
                                Type: UnivariatePolynomial(x,Integer)

q := (1 - 6*x + 9*x**2)**2
      4      3      2
    81x  - 108x  + 54x  - 12x + 1
                                Type: UnivariatePolynomial(x,Integer)
```

The usual arithmetic operations are available for univariate polynomials.

```
p**2 + p*q
      7      6      5      4      3      2
    1458x  + 3240x  - 7074x  + 10584x  - 9282x  + 4120x  - 878x + 72
                                Type: UnivariatePolynomial(x,Integer)
```

The operation `leadingCoefficient` extracts the coefficient of the term of highest degree.

```
leadingCoefficient p
    18
                                Type: PositiveInteger
```

The operation `degree` returns the degree of the polynomial. Since the polynomial has only one variable, the variable is not supplied to operations like `degree`.

```
degree p
    3
                                Type: PositiveInteger
```

The reductum of the polynomial, the polynomial obtained by subtracting the term of highest order, is returned by reductum.

```
reductum p
      2
    60x  - 46x + 8
                                     Type: UnivariatePolynomial(x,Integer)
```

The operation gcd computes the greatest common divisor of two polynomials.

```
gcd(p,q)
      2
    9x  - 6x + 1
                                     Type: UnivariatePolynomial(x,Integer)
```

The operation lcm computes the least common multiple.

```
lcm(p,q)
      5      4      3      2
    162x  + 432x  - 756x  + 408x  - 94x + 8
                                     Type: UnivariatePolynomial(x,Integer)
```

The operation resultant computes the resultant of two univariate polynomials. In the case of p and q, the resultant is 0 because they share a common root.

```
resultant(p,q)
      0
                                     Type: NonNegativeInteger
```

To compute the derivative of a univariate polynomial with respect to its variable, use the function D.

```
D p
      2
    54x  + 120x - 46
                                     Type: UnivariatePolynomial(x,Integer)
```

Univariate polynomials can also be used as if they were functions. To evaluate a univariate polynomial at some point, apply the polynomial to the point.

```
p(2)
    300
                                     Type: PositiveInteger
```

The same syntax is used for composing two univariate polynomials, i.e. substituting one polynomial for the variable in another. This substitutes q for the variable in p.

```

p(q)
      12      11      10      9      8
      9565938x - 38263752x + 70150212x - 77944680x + 58852170x
+
      7      6      5      4      3      2
      - 32227632x + 13349448x - 4280688x + 1058184x - 192672x + 23328x
+
      - 1536x + 40
                                     Type: UnivariatePolynomial(x,Integer)

```

This substitutes p for the variable in q.

```

q(p)
      12      11      10      9      8
      8503056x + 113374080x + 479950272x + 404997408x - 1369516896x
+
      7      6      5      4      3
      - 626146848x + 2939858712x - 2780728704x + 1364312160x - 396838872x
+
      2
      69205896x - 6716184x + 279841
                                     Type: UnivariatePolynomial(x,Integer)

```

To obtain a list of coefficients of the polynomial, use coefficients.

```

l := coefficients p
    [18,60,- 46,8]
                                     Type: List Integer

```

From this you can use gcd and reduce to compute the content of the polynomial.

```

reduce(gcd,l)
      2
                                     Type: PositiveInteger

```

Alternatively (and more easily), you can just call content.

```

content p
      2
                                     Type: PositiveInteger

```

Note that the operation coefficients omits the zero coefficients from the list. Sometimes it is useful to convert a univariate polynomial to a vector whose i-th position contains the degree i-1 coefficient of the polynomial.

```

ux := (x**4+2*x+3)::UP(x,INT)
      4
      x + 2x + 3

```

Type: UnivariatePolynomial(x,Integer)
